VOLUME XXVII
Number 1.

Safety Apparatus, by A. and L. Denayrouze.*

At the beginning of February, 1873, there were made in the catacombs of Paris experiments with a safety apparatus which the inventors named Aerophore. There were present when the experiments were made about fifty persons, among whom were the Inspector General and the President of the General Council of Mines, Mr. Gruener.

In a roomy place provided with benches for the spectators was a cabinet, of which the wall turned towards the spectators had several panes of glass, and the opposite wall had a door provided with a lock. Inside the cabinet were four rows of burning candles, one above the other, and after a couple of chickens and a rabbit in cages had been placed in the cabinet, a man entered through the door, which he locked behind him, with a safety apparatus on his back and a burning lamp in his hand. The apparatus was connected by means of a hose with a compressing air pump. Outside was an apparatus containing carbonic acid gas. This gas was let into the cabinet through a hose; the flow of gas could be distinctly perceived. Soon the lowest row of lights went out, then the second, then the third, and at last the uppermost, hot the workingman with the apparatus on his back continued his work uninterruptedly, the carbonic acid gas notwithstanding, and his lamp kept burning on the level of the already extinguished candles with a bright, steady flame. In the meantime the gas rose to the cages. The chickens died quickly, and the rabbit, placing itself instinctively on its hind legs and holding its nose as high as possible, fell dead to the ground after a few ineffectual leaps. The man continued digging and the lamp kept burning with the same brilliancy. At the close of the experiment the inventors were congratulated by all present, especially by Mr. Gruener.

The reporter of the *Courrier de France*, from whose number of February 4th, 1873, the above description has been taken, regrets that this invention had not until now found that introduction and application which its usefulness deserves. He proposes to invite all owners and managers of mines to these experiments, and thinks that, when they had seen the leaps of the rabbit caused by the pangs of death, they would procure this apparatus immediately, and not, as has been the case until now, buy one after an accident has happened.

As early as 1853 the Academy of Science in Brussels, in the course of its regular business transactions, invited the scientists to make earnest exertions for the discovery of a practical method which would enable the miner with convenience and safety: 1. To penetrate great distances without interruption. 2. To remain. 3. To illuminate, and, 4. To work without restraint in places filled with noxious gases.

About ten years ago Mr. Rouquayrol, mining engineer in Firmy, placed before the mining company in St. Etienne for examination an apparatus to be used in places filled with foal air, for which he received a silver medal.

After there had been made different practical tests, especially in diving with Rouquayrol's apparatus, the brothers Denayrouze again took up the question, and believe that they now have constructed an apparatus which answers perfectly the above requirements.

The principle of the Rouquayrol's and Denayrouze's apparatus consists in making the respiration of the workmen and the burning of the lamps independent of the surrounding air, of whatever nature the same may be. When the distance of the locality worked from a place containing fresh air is not great, only an apparatus of low air pressure is required; but where the air must be obtained from a great distance or from the outside of the mine, or where a large number of workmen are to be supplied, an apparatus with strongly compressed air must be supplied.

The Apparatus with Low Pressure.

It consists of an air compressing pump, of the

epurateur, a contrivance for the purification of air, of an air conducting hose, of the regulator and the lamp. The pump is described in the *Zeitschrift fuer Berg, Huellen und Salinenwesen in dem preussischen Staate*, and here it may be stated, that it supplies with ease air enough for respiration and illumination for two men. A more detailed description is given here of the two new parts, the regulator and the lamp. The epurateur is an improvement of the respiration apparatus.

The function of the regulator *Rr*, in the accompanying engraving, is to supply the workingmen and the lamp with air in proportion to requirements. Its weight never reaches four kilo-

with a mouth-piece of caoutchouc, which exactly fits the mouth and is held between the lips and the teeth. The nose is closed by a clamp which prevents the entrance of the surrounding air. In places filled with smoke a smoke cap with spectacles is used. The breathing hose lies on the shoulder of the miner. To protect it against external injuries, the regulator is placed in a tin box, provided with holes. As soon as compressed air flows into *R* the valve closes tightly, while the tension of the surrounding air acts in the chamber and upon the cover *K*. If now the miner inhales through the hose *L*, a part of the air of the chamber *B*, the tension in *B* is reduced, the outside air

SECOND CANON OF THE YELLOWSTONE.

grammes. The lamp has form and weight of a common safety lamp, but differs from it in the important point, that it does not burn at the expense of the surrounding air, but that it draws its supply from air, free of noxious gas. The regulator consists of a reservoir *R*, into which the air passes by means of a rubber hose screwed to the reservoir. The pressure of air in *R*

presses upon the cover *K* and this causes it to sink, together with the shaft *S*, and thus the valve is opened. The air in the reservoir passes through the opening of the valve into the air chamber *B*, and through the hose to the lungs of the laborers. At the cessation of inhalation the upward pressure in *R* closes the valve and the communication between *R* and *B* is inter-

SAFETY APPARATUS FOR MINERS.

depends on the number of knob lifts (*Kolben-luebe*), and therefore may be regulated. From *R* the air is distributed for respiration and illumination. Over the reservoir is placed a cylindrical air chamber with an open top, but covered with a caoutchouc cap. This cap is fastened to the side wall with an elastic band to establish a perfect closing of the air chamber. By means of a metal shaft *S*, the caoutchouc cap is fastened to a metal plate *P*, which has a smaller diameter than the air chamber. In the wall, between the reservoir *R* and the air chamber *B*, is a conical valve *O*, opening downwards and placed in an opening of several millimeters diameter, by means of which the communication between *R* and *B* is established. From the air chamber *B*, leads a rubber hose to the mouth of the laborer. The end of this hose is provided

ruptured during exhalation. The exhaled air partly returns through the hose to the air chamber *B*, but the greater portion escapes through a caoutchouc valve *N*, composed of two pieces of caoutchouc, and so connected and constructed as to be closed by inhalation and open by exhalation.

The conveyance of the air to the lamp takes place in the following manner: There is connected with the reservoir *R* a smaller one, *r*, over which there is an air chamber, but of smaller dimensions, for the requisite of air for the supply of the lamp is less than the quantity needed by the man for respiration. The construction of the air chamber *b* is in all respects like that of *B*, with but one exception: there is placed over it a cylindrical cover, *H*, to prevent the access of external air. The com-

munication of the reservoir *R*, with the space between the air chamber *b* and the cover *H*, is effected by means of a cock, *R*, turning both ways and bearing on its upper end a hollow nut, *a*. In the position of the cock in the drawing the reservoir *R* communicates with the nut *a*, and the communication of said reservoir with the space under the cover *H* is intercepted. In this manner too much air cannot pass into the space under the cover *H* from *R*. With every turn of the cock a sufficient quantity of air is admitted into the nut; hence, from the number of revolutions of the cock the quantity of air under the cover may be calculated. Moreover, the dimensions are so chosen that a single revolution admits a sufficient quantity of air. The screw *T*, in the middle of the cover, serves the purpose of increasing or decreasing the pressure of the air, besides leading away the compressed air and regulating the supply of air for the lamp. A hose, *X*, leads from the small air chamber, *b*, to the lamp. When a part of the air coming from *b* is burned, and the quantity of the air, and with it the pressure in *b*, is decreased, the compressed air enclosed under the cover, *H*, presses downwards the caoutchouc cap, together with the metal plate and shaft, the valve opens and air flows from *R* into *b*, and thence through the hose to the lamp. In this manner the lamp receives its uninterrupted supply of air.

Scenery on the Yellowstone.

The second canon of the Yellowstone is described by Prof. Hayden as being carved out of a lofty range of mountains by the river. A sketch taken in this canon is shown on this page. The canon was undoubtedly started in a fissure, but is mostly one of erosion.

It is about three miles long. This is, of course, an extension of the range of mountains in which Emigrant gulch is located, and it undoubtedly contains mines of gold. The rocks, with their peculiarly distinct and contorted strata, as well as texture, remind one of the gneissic mountains in the mining districts of Colorado. The river rushes with considerable force over the loose masses of rock that have fallen into the channel, and presents a picturesque view to the traveler struggling along over the narrow trail, high up on the mountain side. But wherever the water forms an eddy, so that it is even moderately quiet, the number of fine, large trout that can be taken out within a limited period, would astonish the most experienced fisherman. Above the canon the rocks return at once to their igneous character. This is readily shown by the difference in the appearance of the surface features. Although the granitic portion is higher and more massive in its general aspect, yet the surface is rounded and much of it covered with debris that admit the growth of grass, while the volcanic rocks give a jagged ruggedness to the outline. Outflows of dark brown basalt, apparently of late date, mingled with huge masses of breccia, can be seen on either side of the valley to the summits of the mountains. The foot-hills on either side are certainly composed of breccia for several miles, which, decomposing, gives to the surface the appearance of the remains of an old furnace. Perhaps it would be better to compare it to a modern volcanic district.

SOUTH MOUNTAIN.—The Idaho *Avalanche* says: South mountain to-day is a "busted" burg, financially; business is almost entirely suspended. The streets are no more lively than the streets of ancient Thebes. Not four months since there were a thousand men in and around this camp, heavy freight teams were seen on our streets every day, business was good, prospects were encouraging, and everybody making money. But to-day not more than sixty men remain to tell the tale of by-gone days. The streets are deserted, the musical voice of the bull-whacker is among the things that were. Only an occasional hummer ventures out and wends his way to the nearest gin-shop to sponge a drink, and rarely gets it. Notwithstanding the gloomy outlook the people, what there is left of them, have not given up all hopes that the camp will be all right again in the spring.

SETH McCAIN, one of the pioneers of Nevada died on Tuesday.

*Translated for the PRESS from *Oesterreichische Zeitschrift fuer Berg-und Huellenwesen*.

CORRESPONDENCE.

Krom vs. Rittinger.

MESSES. EDITORS:—Pending the publication of my description of the concentration works at Falun, there appeared in your paper a well written article on concentration, by Mr. Samuel Purnell, which evinced the possession of correct knowledge and views in the art on the part of the writer—as regards the general principles involved, at least.

As Mr. Purnell undertakes, however, to champion the claims of the Krom dry concentrating jigger, and the system of dry concentration in general, in opposition to the system of wet concentration as developed by Rittinger, and the apparatus therein used, I venture to object to some of the arguments used to defend his position, as tending to prejudice the less informed readers of your paper against a method of ore dressing, the inferiority of which, as compared with dry concentration, must be proven by more than the opinions of a few persons who cannot claim any very extensive experience in either method of ore dressing—for want of opportunity to attain it—or by half stated results of a few, to all appearances imperfect experiments.

One of the arguments used to prove the inefficiency of the Rittinger system was, that works having been built on that system at a cost of \$300,000 had proven a failure.

Now, the very circumstance of parties expending such a sum of money in the erection of works, without first assuring themselves by careful preliminary experiments on a limited scale, of the capabilities of the system to be adopted, is proof sufficient that those parties did not understand their business, and leads to the inference that there were other causes of failure than the choice of an unsuitable process merely. As well might the argument stand, as used in Colorado, that, because rudely constructed Rittinger percussion tables did not give satisfactory results, that kind of machine was not suitable for the treatment of the peculiar class of ore.

Those who have witnessed the operation of dozens of these machines in the extensive concentrating establishments of Europe, on a great variety of the ores of lead, copper, silver, gold, zinc, cobalt and nickel, tin, iron, and the separation of stone coal from slate, with uniform success, and who have further proof of their efficiency, in the reliable and detailed statements of results obtained during months and years of regular work, establishing the capabilities of the machines beyond a doubt, will not be convinced by such arguments as those cited, but will demand proof resting on as sound a basis as their information to the contrary.

Granting, in part at least, the theoretical premises claimed as favoring the use of air in place of water, it may still be asked, what becomes of that part of the valuable mineral, which, after the crushing between the rollers, is still found enclosed, in a gradation of quantity, in the various classes of coarse and fine sands, and which can only be made available to concentration by a finer pulverization of the particles of ore.

It is a well established fact, that rollers will not crush fine for any length of time, and that the bulk of the product from their action is in the form of coarse sand. Still, there seems to be no provision of other machinery for this further pulverization in the Krom system, as illustrated by Mr. Purnell.

To claim that this was found unnecessary because the coarse jiggling wastes were found to be sufficiently impoverished, would merely indicate that Mr. Krom, in such instance, was under obligations to a rare freak of nature, favoring the results from his system. With the majority of ores it would be found as elsewhere, that only a part of the jiggling wastes would be sufficiently impoverished to be passed off, while a considerable amount of intermediate products would result, too poor for admixture with the concentrates, and too rich to be run into the waste sluice; their further utilization makes their further disintegration an imperative necessity. To assert that rollers are suitable for this work, would be a silly taunt in the face of experience. Rollers are also uneconomical for fine crushing, in consumption of power and wear.

It is further argued, that the lesser density of the air facilitates the separation in the jiggling operation. This is true in the jiggling of the coarse classes, which are sized in the wet method also; in the fine grades it is different, the separation depending on the action of inertia of particles of varying size and density, in rapidly ascending and descending currents of water, during short periods of time, in which the density of the water favors the separation. When this can be contradicted, with proof as convincing as is given for the law by Rittinger, then we will be ready to heed the arguments. It will also be remembered, that this law is not a theoretical assumption merely, but has been proven practically correct, by the improved results obtained of late years with the rapidly working fine sand jiggers, arranged to act in accordance with the above mentioned law. The

results obtained with jiggers making 200 and more strokes per minute, are also a practical refutation of the assertion made by Mr. Purnell, in regard to the admissible number of strokes in the water jigs.

It is also urged, that the greater number of strokes in the air jiggers gives them a superior capacity. This favors the separation; but this working capacity in the water jig does not depend on this alone—the working off of this waste sands has equal or more influence on the capacity and will certainly be effected most rapidly by the denser medium, the current of water, with its greater force of impact.

That the separating action in the water jigger is ample, is proven by the products obtained in a machine with only two compartments. The product from the second compartment is found so poor as to require re-working, showing that the bulk of the mineral to be separated has gone down in the first compartment. The presence of ore particles in the second compartment cannot be ascribed to imperfect separation altogether, but is mainly due to the unavoidable differences in the size and density of the particles under treatment, differences which cannot be avoided within the practicable limits of sizing and grading, and which will assert themselves in any system of concentration, and deteriorate the results obtainable with any machine.

Even if the Krom jigger were to be proven a machine capable of separating these intermediate products with the richer concentrates, in consequence of the lesser difference of density required for separation in the less dense medium air, this would not in all cases satisfy the requirements, because the admixture of the middlings would often make the products too poor for the attainment of the greatest profit. In the wet concentration these middlings are subjected to a further pulverization, and the valuable mineral thereby liberated from the rock, extracted with further appliances found most suitable.

Moreover, I have not seen any well authenticated statement of guaranteed results, giving the working capacity of the air jig in the form of figures. The wet jiggers of the newer construction will concentrate from four to fifteen tons of sand and gravel per day, according to the size of grain and the mineral to be separated. What can be guaranteed to be the capacity of the Krom jigger on the different sizes of grain to the working of which it has been found adapted; and what is the finest class or size it will work?

It is also intimated that the Krom jigger can be put up for a less price than water jiggers of the same capacity—the cost of the former being given at \$500. To this I will reply, that when I have finished my present work of fitting up the machinery department of the Boca Lager beer brewery, I will be prepared to furnish water jiggers, possessing the merits of the most approved machines, for \$500, and will guarantee them to do more work than a Krom jigger on the same grade of ore will do, with an equally satisfactory separation.

True, the water jigger finds its limit of excellence in the decreasing size of the particles, and in the case of particles sifted through screens finer than thirty to forty meshes to the linear inch, it is superseded by other appliances of greater efficiency. To what extent the Krom jigger can compete with these, I have no information definite and reliable enough to make a comparison. Granting that the air jigger can equal these even in the treatment of the finest grades—for which there is no sufficient proof—the dry system has still to cope with the difficulties of dry sifting through fine screens, a slow and imperfect operation, when compared with the rapid and efficient system of grading with the aid of ascending currents of water, especially when considered in connection with the economical advantages of wet stamping in batteries with a dammed water discharge.

One of the chief advantages of the dry system seems to be the saving of the finest particles, which being thrown into spacious dust chambers, will certainly deposit from air much more rapidly and perfectly than they would in water. Still, even this advantage applies to a limited class of ores only with such force as to outweigh the economical advantages of wet concentration.

With a judicious system of gradnel fracture, the proper use of the "Stausatz" battery, and well arranged slime tanks of sufficient capacity, the loss through floating away of the finest particles, in the case of any ores except those containing the very frangible silver minerals, can be reduced to a trifling amount. The loss caused by insufficient liberation (by pulverization) of the mineral to be saved, will in most cases far exceed the loss by float. Certainly, if Mr. Purnell takes the loss by the wet system, by the reported results obtained ten to fifteen years ago, with the arrangements then in use, the showing will be less favorable.

As an isolated example of the performance of the dry system with the Krom machine, etc., Mr. Purnell mentions the results obtained in Star district, Nevada, where, it is claimed, ninety-five per cent. was saved in the concentration of a silver ore. Unless a more satisfactory statement can be made of the work there done, than is contained in the Report of the U. S. Commissioner of Mining Statistics, I beg to submit that the test is not very convincing. The values obtained, as there reported, when summed up, lead to the inference that the ore must have become richer in the course of treatment, or else the determination of weights and values be far from accurate, or the saving of rich fine dust—the principal ad-

vantage of the system—must have been insignificant comparatively. So, at least, it must appear to the impartial, calculating reader, until a more satisfactory statement is given.

I do not wish to detract from the real merits of the new system, and the Krom machine, for I am assured by good authority that it does good work, and cannot but admit its great value in numerous districts in this country, where the scarcity of water makes wet concentration difficult or even impossible. When, however, the disciples of the Rittinger system are requested to renounce the predilections attained by experience and observation, in such works as those of the Harz, Altenberg, Stolberg, Ems, Pozibram, Falun, and many others, in the treatment of almost every variety of ore, then it may not be considered presumptuous, if they demand more positive, accurate, detailed and repeated proof of the superior efficiency of a new system, than has hitherto been presented, regarding the results obtained with the dry system by the aid of the Krom jiggers, etc.

When such proof is given that the problems of an art assiduously studied for centuries, and always considered difficult, have found a solution at once so simple and efficient, then none will be more ready and willing to welcome and proclaim it a benefaction to mankind, than those who have a thorough appreciation of the shortcomings of the wet system of concentration.

CHARLES C. RUEGGE.
Boca, December 21st, 1875.

The Kossuth Mine and Machinery.

The Lyon County Times says of the mine and its machinery: The building which covers the hoisting machinery is strongly and plainly constructed, with no attempt at elegance or show. The main structure is forty by eighty feet on the ground, and twenty-five feet high in the clear. Adjoining it on one side is a large carpenter shop, and on the other a blacksmith shop, where all the necessary blacksmithing and carpentering is done for the mine. The machinery of the mine consists of double hoisting engines of sixty horse-power, a pumping engine of eighty-horse power, one 54-inch and one 60-inch boiler—each sixteen feet long and having sixty-four three inch flues—all of the very best and appropriate to the work in hand. The shaft is supplied with an eight-inch pump, with six feet stroke, which keeps a constant stream of thirty-six inches (miner's measure) of water flowing from the mine. Two wire cables, three and one-half by one-half inch are used in hoisting the cages and tanks. At a depth of 200 feet in the shaft a "balance bob" has been placed to regulate the workings of the pump. The shaft is of three compartments. At the 200-foot level a drift has been run west through solid rock, and cutting the ledge at a distance of 450 feet from the shaft, the vein being fully 200 feet wide at this point, the ore of which mills from \$7 to \$12 per ton, although some of the assays run as high as \$30. From this drift a north level has been run along the west wall a distance of 450 feet to the south line of the Dayton company's ground, which the Kossuth adjoins, and a south level driven in on the wall 800 feet, opening the vein a total distance of 1,250 feet. The ore and ledge matter for the entire length of the north level is of the same quality as where the drift cuts the vein. In the south drift there is a steady and rapid change in the character of the vast mass of mineral for the better, and at a distance of 300 feet it has changed almost entirely. It has here turned into the true white, silver-bearing rock, being a faithful representative of the upper Comstock rock. At various distances cross drifts have been run east to prospect the vein, and have demonstrated that not only the width of the vein is uniform throughout, but the quality of ore also. At the 350-foot level the ledge has been cut by a west drift of 220 feet, and the vein is found to have narrowed from 200 feet to 80 feet wide, with rapid contraction. The vein matter has grown compact and presents a still better quality of ore, with walls and blue clay casings as perfect as one would have made them himself, had he the power. The genuineness of the fissure is abundantly proven both on this and the level above, as well as the 500-foot level below. At the 500-foot level a west drift of eighty-six feet has been run to the ledge, which is here found to be eighty-five feet, or nearly the same width as at the level above.

IMPROVED METHOD OF TEACHING THE ALPHABET.—M. Tholhoie has, authorized by the French school inspector, applied in the primary schools in Paris his improved method of teaching the alphabet and reading. It is done by the help of a small wooden box, divided into compartments, each holding a letter, sign, or figure. Each scholar has such a small box, and the teacher a much larger one. The teaching is done by naming a letter, say A, and the teacher takes it from his box and shows it to the class; each pupil does the same, and places his letter on the inside of the cover of his box, which, when opened, turns over like a desk. In this way the child is forced to give attention, while he is entirely occupied with eyes, mind, and hand. The experiment of M. Tholhoie has already proved eminently successful. In the first school he undertook to teach, twenty-five children were given him totally ignorant of their letters, and in two days fifteen of them knew them tolerably well. But after this the greatest advantage commences, namely, letting the child form his words with the letters. Such alphabetical blocks are sold as useful toys for children in most of our toy stores, and they should be more extensively used by teachers in all our primary schools.

Opening for Mining Enterprise.

One of our oldest and most intelligent miners, says the *Mountain Democrat*, (El Dorado county,) who has with eminent success handled big enterprises, makes the following suggestions:

Everybody is aware of the immense gold-bearing gravel range in this vicinity. As an outlet for hydraulic operations on this grand deposit, attention has been directed towards Webber creek, and it is already manifest that the operation of a few years will make several miles of cutting and tunneling necessary to obtain adequate dumpage in that direction. Now, it is pretty generally known that a monster quartz ledge—the "mother lode" of this entire section—crosses from Cedar ravine to Big canon. A tunnel started from a point on Big canon, nearly opposite the flume which crosses the road beyond Hunger's slaughter-house, and follow the mother lode on a good slanting grade, would probably be about one hundred feet below the bed of Hangtown creek where it would cross the line of that stream, would completely drain the Pacific and adjoining quartz claims, and would tap the great gravel range at a point from which thirty million cubic yards of rich gold-bearing gravel might be run through it, affording unlimited dumpage, the best in California, on the high and steep hills which tower to the southward of the South fork. Our miner friend thinks this tunnel would not need to be more than 3,000 to 3,500 feet in length. He is sanguine that the quartz taken out in running it would fully pay all expenses, with more than a probability that a No. 1 quartz mine or mines would thereby be developed and opened in good shape for profitable working, the flume carrying off the waste and a track carrying the pay rock to a mill or mills at the mouth of the tunnel.

We confess that these suggestions have excited our lively interest. We commend them to the further consideration of our capitalist friends.

Quartz Mining in Montana.

This *Montanian* of a recent date says: There is no question that much of the future prosperity of Montana will depend upon the development of the mineral deposits that are looked up in the quartz lodes which abound in this Territory. But it is certain that many of these lodes cannot be worked profitably by those who claim the ownership of this property, and unless the aid of capital can be secured for opening the mines and reducing the ores contained therein, the richest veins are comparatively worthless. It has been the experience of the past that whenever capitalists have wished to invest in property of this description, it has been held at such fabulous figures as to discourage and disgust those who could by their money and influence reveal some of the hidden wealth of our Territory. The writer can recall to memory many instances in which the owners of quartz lodes could have disposed of their possessions for what would be considered a moderate competency, but refused the offer, and to-day the mines which might have been developed are lying in the same condition as when they could have been sold to parties who were able to develop them, and test their producing capacity. It is a fact that the mines of Montana are now attracting the attention of Eastern and Western capitalists to a greater extent than ever before—except, perhaps, during the time of the great mining excitement of '63 and '64—and it is very likely that the next traveling season will bring many such to the country with a view to investing in them. There are very few places in the Territory where the work of opening quartz mines cannot be carried on as rapidly in the winter as in the summer, and owners of this kind of property will do well to put it in such shape as will make a favorable showing to intending purchasers. The day has gone by when men will invest a fortune in mines on the mere showing of a piece of float ore, or a cradle on the surface where quartz may be found; but wherever the prospector can show that he possesses a mine that will pay a reasonable percentage upon the cost of working, he can rely upon soon finding a purchaser for his property, provided he does not hold his breath too long while considering the length of the buyer's purse. The practice of "bleeding" capitaliste to the greatest possible extent has done more to retard the progress of Montana than perhaps any other thing; but we believe that our people are awakening to the truth that undeveloped quartz is worse than none at all, and that the owner has the biggest kind of an elephant upon his hands. If our miners go to work and show that they have good ledges, and then sell them at reasonable prices to those who have the will and ability to work them, we shall soon see such an impetus given to this branch of mining industry as will place Montana in the front rank of money-producing countries.

IMPORTANT OUTLOOK FOR GAS FUEL.—The iron makers of England are very much astonished at the success attending the use of natural gas, in metallurgical operations at Pittsburgh; and the indications are that our English cousins will soon apply artificial gas fuel to some of their furnaces. A rotary puddler will probably be the first with which they will experiment. If that succeeds, we shall soon hear of the further and more general application of gas fuel.

MECHANICAL PROGRESS.

Engines for Steep Grades.

On railroads where steep grades have to be overcome, it has been the general practice to detach the locomotive and to haul the train up the incline by the aid of wire ropes moved by a stationary engine placed at the top of the hill. If the grade is not too severe, the locomotive is commonly able to take itself up the incline. Where this is possible, two novel modifications of this idea have been introduced, and the locomotive takes the place of the stationary engine. In each system a rope and winding drum is used. In one the drum is fixed on the engine, in the other the drum is fixed at the top of the incline. By the first method the engine is provided with gripping struts that, on being let down, grip the rails and anchor the engine securely. The winding drum is fixed to the frame of the engine, and has the wire rope wound up on it. On reaching the foot of the grade, the engine is detached from the train, the end of the rope is secured to the first car, and the engine mounts the incline to the top, or as far as the rope will permit. The gripping struts then anchor the engine, and, on applying power to the drum the train is hauled up. If the top of the grade is not reached, gripping struts are applied to the cars, and the engine goes and repeats the operation. The grade being overcome, the engine is again coupled and the train continues its journey. By the other system, the winding drum is fixed in a sunken pit at the top of the incline, and is provided with a wire rope for dragging up the train. This winding apparatus is provided with four driving wheels coupled in pairs, and so placed as to have their upper surface just level with the tracks. A gap is left in the rails over each wheel, so that it may turn freely. On reaching the foot of the incline, the engine mounts the hill alone and runs over the winding drum till its four driving wheels exactly coincide with the wheels of the drum. In fact, it rests upon them, and is locked in that position. The wire rope meanwhile is secured to the train. On starting the engine the driving wheels turn those it stands upon by friction, and in place of moving outward it stands motionless and turns the winding gear. By this simple means the train is dragged up the incline till it rests upon the higher level. The engine is then unlocked, and joining its train on the main line, it resumes its duty. On descending the grade, both train and engine are lowered in safety by the rope under the control of a brake on the winding drum. Both of these systems are still in the experimental stage.—*Scribner's World's Work.*

STREET RAILROAD TRANSIT.—The municipality of Paris, though slow in adopting street railroads, seems to be making rapid improvements in motors for propelling the cars since such railroads have been adopted. Successful experiments were first made on a line between Porte Maillot and the bridge of Neuilly with a new machine driven by compressed air, which took the cars at a high rate of speed with a small power, and with easy management in quickening, slowing or stopping. More recently successful experiments have been made with still another dummy, driven by steam and with coke as a fuel, the inventor being Mr. Harding, an Englishman. Of one experiment with it the *Correspondance Havas* says: "A car containing forty-four persons, all of them comfortably seated, was drawn by this dummy from the Place St. Germain-des-Près, over the line of the southern tramways of Paris through the Rue de Rennes, the Boulevard Montparnasse, the Avenue d'Orléans and the Avenue de Châtillon, to the fortifications. The trip occupied sixteen minutes going (up hill) and twelve returning, and was performed at the rate of twelve kilometers, or about seven and a half miles an hour. The speed of the dummy was completely under control; the car was stopped and set in motion more easily than with horses, and the horses in the street were not in the least disturbed by the engine. The authorities expressed their entire satisfaction with the experiment."

THE USE OF PETROLEUM IN DRILLING.—We have already, in these columns, made reference to the use of petroleum in drilling, and we now copy the following from the *Messageur Franco-Américain* of New York: "A curious effect of petroleum has been discovered. It is well known that the boring or turning of certain pieces cast from very hard metal, like steel and varieties of bronze, is a most difficult operation; often the best tools cannot be got to make an impression on the metal; they get soft or break without producing any practical effect. It now seems that an English engineer has discovered that steel tools, continually oiled with petroleum, or a mixture of petroleum and spirits of turpentine, will drill without difficulty the hardest alloys of steel or bronze. This discovery is important at this precise moment, when a new artillery is being made of steel or compressed bronze, called Uchatius bronze, after the inventor, an Austrian officer."

THE DANKS FURNACE.—It is stated by the *American Manufacturer*, that Mr. Danks is now in Birmingham instructing his lawyers preparatory to commencing suit against Mr. Crampton for using, in his furnace, inventions embraced in the Danks.

A NEW SYSTEM OF PRISON CONSTRUCTION.—The *Popular Science Monthly* describes a new system of prison construction, which has recently been covered by a United States patent. We extract as follows: "The cells are lined with the hardest cast iron, the doors, windows, frames and sashes being of one piece with perforations. As wrought iron is easily cut and filed, there is none of it used. The plates are connected without bolts or rivets. Any attempt of a prisoner to escape by cutting the walls of a cell is checked at once by the hollow wall system. The space in the wall, door and ceiling is filled with kiln-dried sand, or other mobile material, which runs through an outlet by an opening that might be made, rendering it impossible for any prisoner to dispose of the same. An inexhaustible supply of this sand is furnished by a hopper constructed near the roof of the building or on top of the cells. Brick or wood walls, and single or double iron lining can be used for this system. In addition to the last mentioned plan, an alarm apparatus is connected with the sand, so that any noise or disturbance arising from cutting in any portion of the cell, is instantly heard in any part of the building. There is no limit to the number of places at which such alarms can be given simultaneously. In general, the system is ample and complete in all its details, and is well worthy attention of cities, counties, States and general governments requiring prisons of any grade of construction or cost."

NEW MODE OF MAKING BOLTS' NUTS.—Puddled bar is rolled into the required shape to make a hollow pile, by forming two sides with top and bottom of half circle, octagonal or hexagonal, exterior or hollow fagot, just as may be desired. This pile is heated in the usual manner, and before being given to the rolls, a mandril is introduced into the exterior or hollow of the pile, which mandril is held in position by being attached to the end of a rod or chain, the other end of which is supplied with a collar, which falls behind a notched rest or brace, which holds the mandril in place as the pile is introduced to the bite of the rolls, and passes through them. Thus the exterior of the bars and the interior are formed at the same time, and the weld completed. The further reduction and finish of the bar is accomplished by a repetition of the manipulation in the successive use of smaller mandrils and smaller grooves in the rolls. Then, before the bar has lost the heat, it is given to a gang-saw, and by one movement cut up into blanks of the required thickness, of exactly uniform size and weight, ready for the reamer and milling and chamfering machine. It is claimed that nuts can be manufactured much cheaper by this process than by the old methods; they are stronger, and consequently can be lighter, and thus more of them obtained from a given weight of iron.

NEW MATERIAL FOR BUILDING.—A material suitable for blocks and bricks is, according to the invention of Messrs. Smith and Patterson, of Glasgow, made from two mixtures. The first contains coal tar, mixed with small broken stones or shingle, a portion of which should be pulverized or mixed with sand, so that the interstices between the stones of larger size may be properly filled up. The second mixture is composed of clay and pitch; sand or chalk may be substituted for the clay. The first mixture is mixed in a mixing apparatus at a heat which is gradually increased until the product is adhesive to the touch. The second mixture is formed by grinding the powder thus obtained, and is added to the first mixture while its particles are adhesive to the touch. The mixture of the two compounds is confined in a close vessel and heated so as to diffuse the vapors uniformly throughout the ingredients. In manufacturing a building block, the material having been tested is removed while hot to moulds, and pressed and shaped as required.—*The Builder.*

HOW TO APPLY A LEATHER COVERING TO AN IRON PULLEY.—Upon the question how to apply a leather covering to an iron pulley, some light may be shed by the following description of a process by which it is said that leather may be affixed to a metal so that it will split before it can be torn off. A quantity of nut-galls, reduced to powder, is dissolved in eight parts of distilled water, and after remaining for six hours is filtered through a cloth; and the decoction thus produced is applied to the leather. Take the same quantity of water as that used for the nut-galls, and place in it one part (by weight) of glue, which is to be held in solution for 24 hours, and then applied to the metal, which should first be roughened and heated. The leather is then laid upon the metal and dried under pressure.

INDESTRUCTIBLE TRAINS.—Mr. David Robertson, 79 Robertson street, Glasgow, Scotland, has written to the railway commissioners recommending, as a means of preventing the personal injury and damage to property which result from railway collisions, that passenger carriages should be constructed of strong vulcanized india-rubber, which, he says, can be moulded up to any thickness and degree of elasticity. The carriages would be round at the ends in place of having buffers attached; and these convex ends would become concave in collision, but would not jerk the carriages off the rails like buffers. He proposes that the train should be united by a wire rope passed through eyes underneath each carriage to a windless on a brake behind, which would tighten it up to any tension.

SCIENTIFIC PROGRESS.

The New Element—Gallium.

We have already in these columns made allusion to the new element named gallium, which has recently been discovered by M. Le coq, an amateur French savant. It was discovered through the agency of spectral analysis. Its spectrum is two bright lines in the violet region. One of these, slightly brighter than the other, is in the 417th degree of the scale, the other is at the 405th degree, and both in the place occupied by the brightest lines of zinc. Chemical analysis shows that it is closely related to that metal. It has not yet been isolated, and is known thus far only as a chloride and sulphate.

Up to the present time only a very small quantity of gallium has been obtained, but M. Wurtz, who presented a paper on the subject before the French Académie des Sciences, has given to some members tubes of solution for experiment; and on asking for a commission to examine into the question and to place gallium on the list of simple bodies, the Academy named M. Wurtz himself, joining with him M. Fremy.

Pending the decision of this commission, a question of doubt has been thrown upon the reality of this reported discovery. The *Boston Journal of Chemistry* alludes to the fact that even indium has not yet been fully established as a new metal, and adds: But we should almost suspect the identity of this supposed new substance with indium: 1. Because, as mentioned in the report in regard to this new metal, the other metals discovered by the help of the spectroscopy, thallium, caesium and rubidium are mentioned, but indium is ignored. 2. Indium also produces two lines in the violet, one very bright and the other more faint. 3. Indium was also obtained from zinc blende, namely, that of Freiberg in Saxony. 4. Indium has thus far only been obtained in small quantities, and its properties have been imperfectly studied thus far; as it forms a new field for investigation, we are surprised that Prof. Wurtz, so famous in new researches, appears to ignore it.

If the accounts are correct, however, gallium differs from indium in this respect, that an excess of ammonia redissolves the precipitate of hydrated oxide of gallium first formed, while in the case of indium the precipitate of its hydrated oxide is not redissolved by an excess of ammonia. We look with interest for further reports regarding this supposed 65th element.

THE GERMINATION OF SEEDS IN ICE.—Some interesting experiments on the growth of seeds have been conducted by M. Uloth. These were undertaken with a view to determine whether seeds could be made to germinate in ice, and the process may be described as follows: Seeds of various species were placed in grooves made in ice cakes, and over the grooved surface other plates of ice were laid, and the whole removed to a cool cellar in January, and there they remained till the following May. An examination then made disclosed the fact that many of the seeds had actually germinated, the roots penetrating into the ice. It is but natural, says *Appleton's Journal*, that facts of this startling character should give rise to controversy, and so we are not surprised to learn that opposite views are entertained as to whence the heat needed for the process of growth was obtained. In the opinion of the experimenter, it was obtained, or rather liberated, in the growth of the roots while forcing themselves into the ice.

THE GENESIS OF ATOMS.—Dr. Henry Muirhead recently read a paper before the Philosophical Society of Glasgow on "the Genesis of Atoms, Worlds and Sun-spots," in the course of which he argued in favor of the theory that atoms are formed from ether, molecules from atoms, masses from molecules, and worlds from masses, all matter having originally been of the same character. From the absence of sun-spots in the periods after Jupiter has been at the point in his course nearest to that portion of space through which the sun next travels, he argued that Jupiter influenced the absence of these spots, his explanation of the phenomenon being that the planet at these parts of his course influenced matter floating in space which would otherwise have gone to cause sun-spots. Incidentally in the course of his paper, Dr. Muirhead expressed his belief that the origin of motion was coeval with the origin of matter.

A GAS SHADOW.—A striking and curious experiment, showing the superior weight of carbonic acid over air, may be made by projecting the shadow of the gas, as it is poured from its containing vessel, upon a screen. The latter should be of white paper and bright sunlight should fall upon the stream of gas, which should be poured from the spout of a pitcher held within ten inches of the screen. The curious result of a shadow produced by apparently nothing, will be seen, the former resembling descending smoke, quite black at the spout of the vessel, but brightly illuminated whenever the sunlight is concentrated by passing through the gas.—*Scientific American.*

How Far Will Bodies Sink in the Ocean?

The often repeated inquiries which we receive, as to the depth in the ocean at which heavy bodies will float, prove the great prevalence of the error that water is so compressible as to become at certain great depths considerably heavier, by its own superincumbent weight. The fact is that, on the contrary, water is one of the least compressible bodies, so that, under a pressure of 7,200 pounds per square inch, corresponding to a depth of three miles, its bulk is only diminished from 1,000 to 978 parts, and its weight or specific gravity increased from 1.000 to 1.022. At double this pressure, or 33,600 pounds per square inch, at six miles in depth, the compression is double that amount.

If a body be capable of floating at such a depth, it must satisfy two conditions: First—Its specific gravity must be between 1.000 and 1.044. If the specific gravity is not more than 1.000, it will not sink at all; and if it be 1.044 or above, it will sink to any bottom less than six miles deep. Second—The sinking body must be less compressible than water; if it is more compressible, it will grow comparatively heavier all the time it is descending, and can never find a stratum of the same weight, in which it might float in equilibrium. Now all the bodies known to be less compressible than water are much heavier than the limit given; such are stones, metals, etc.; and the amount of their compressibility, as compared with that of water, is still problematic. But they will certainly all sink to the bottom of the ocean, he it ever so deep.

In regard to the bodies of which the specific gravity surpasses that of water slightly, so as to come within the range under discussion, they are all very compressible. All kinds of wood, when submitted to great pressure, so that all the pores are filled, attain the specific gravity of the primitive wood fiber, the lignin, of which the specific gravity is 1.400; and they will sink to the very bottom, like water-logged wood. So it is with all similar substances; and the theory that there is a certain depth in which all or many bodies may float in the ocean must be modified to a statement that there are various depths at which certain bodies may be kept floating; but that the cases are extremely rare, exceptional and perhaps only temporary, so that all bodies will finally either sink or float.—*Scientific American.*

SIR ISAAC NEWTON'S EXPERIMENTS.—When Sir Isaac Newton changed his residence and went to live in Leicester Place, his next door neighbor was a widow lady, who was much puzzled by the little she had observed of the philosopher. One of the Fellows of the Royal Society of London called upon her one day, when, among other domestic news, she mentioned that some one had come to reside in the adjoining house, who, she felt certain, was a poor crazy gentleman, "he became," she continued, "he diverts himself in the oddest ways imaginable. Every morning, when the sun shines so brightly that we are obliged to draw the window blinds, he takes his seat in front of a tub of soapsuds, and occupies himself for hours blowing soap bubbles through a common clay pipe, and intently watches them till they burst. He is doubtless now at his favorite amusement," she added; "do come and look at him."

The gentleman smiled, and then went up stairs, when, after looking through the window into the adjoining yard, he turned round and said: "My dear madam, the person whom you suppose to be a poor lunatic is no other than the great Sir Isaac Newton, studying the refraction of light upon thin plates, a phenomenon which is beautifully exhibited upon the surface of a common soap bubble."

This anecdote serves as an excellent moral not to ridicule what we do not understand, but gently and industriously to gather wisdom from every circumstance around us.—*Druggists' Circular.*

MORE PALEOZOIC FROGS.—Usually the venerable batrachians which have survived from the carboniferous or a still earlier epoch are discovered in solitary confinement and in a cell no larger than the body of the captive it contains. According to a Glasgow daily paper, however, a perfect swarm of frogs, and what is more remarkable, young frogs, has been found while driving a shaft through sandstone in the Shieldmain coal-pit, Motherwell, at a depth of 330 feet from the surface. Several dozens of young frogs were thus found lodged in the cavity of a stone. The term young, however, can be only comparative when the millions of ages they have lived is considered. What is likewise very remarkable, as soon as they were liberated they betook themselves to a pool of water, where they seemed quite at home, a remarkable instance of inherited instinct or retentive memory.

CONDUCTION OF HEAT BY BUILDING MATERIALS.—The coefficient of conduction for heat of various building materials has lately been carefully investigated by Lang, who, in his studies, has endeavored to exclude the influence of radiation, and has made measurements by means of the thermo-electric multiplier. He finds that the stones considered by him are much better conductors of heat when wet than when dry, and that various classes of stones, such as marble, sandstone, granite, etc., have approximately the same coefficients of conduction, while bricks of all kinds are much worse conductors than the natural stones.

The Mining Share Market.

During the past week stocks have gone up a little, and in some instances considerably. No one can tell yet, however, whether there will be a lively market or not for any length of time. The rise may be only temporary and fall back to its usual status of late; but the brokers and speculators hope to the contrary. News from the prominent mines continues encouraging. The general tone of the market of late has been strong, at advancing rates, but notwithstanding these great appreciations in prices, brokers complain of the scarcity of orders, which is clearly accounted for by the high premiums demanded for money. Accommodations to a slight extent are made, and these small loans receive the same prominence as if millions had been advanced at low rates, so scarce have been these loans. The fluctuations in the market can be seen by reference to our stock tables for each day during the past week.

In the Belcher mine the connection has been completed between the upraise from the 1400-ft level and the air shaft below the 1300-ft level, greatly benefiting the circulation of air in that portion of the mine. The improvement created by this air shaft has been so great that 300 men now perform the work that it took nearly 1,000 to do before the air shaft was started.

Thoreday morning John Bosanco, a miner working in the Combination shaft on the Comstock, fell about one hundred feet, striking on a platform of two-inch planks and crashing through them to the bottom of the shaft, a few feet below. In spite of all this he suffered no more than a cut on the head, a few bruises and three broken ribs.

The etemps in the new California mill, on the Comstock, have 3½ inch etems, being half an inch larger than any before used in the mills of that section. They weigh 900 pounds each. The mill will be supplied with every improvement and convenience that can be devised, and will be a model construction of the kind.

C. C. STEVENSON, president of the Nevada board of Centennial Commissioners, left Virginia last Wednesday for Philadelphia. He goes East to secure the room in the exposition likely to be required by Nevada.

The stockholders of the smelting works at Hamilton are looking into the affairs of that enterprise, which has not answered their expectations, and they allege it is owing to the bad management of the superintendent.

...ing is mostly condensed from journals published in the interior in proximity to the mines mentioned.

HOPE ROCK.—Amador Dispatch, Dec. 10. Notice that Mr. Charles Peters, proprietor of the Good Hope mine, has been engaged several days past in hauling quartz from the mine to the Volunteer mill for the purpose of having it crushed and its richness tested.

mine, at Sutter Creek, about 12 o'clock last night, the 19th, causing considerable destruction thereabouts for a while and resulting in considerable pecuniary damage to the mine, but fortunately no lives were lost. The amount of damage done to the mine is not known, however, as the shafts and tunnels were all closed up as soon as possible after the alarm was given and the men were alerted, in order to smother the fire. The mine is supposed to have caught from a candle which some of the workmen who were engaged in repairing the ladder which was damaged several days ago by the falling of a bucket of

TOWN DITCH.—Oroville *Mercury*, Dec. 10, N. D. Plum, of Forbestown, we learn, has had a fine success in clearing up men have been at work most of the year, so that the coming season it will be a great deal more water than ever before. The work was laid out for this season, this was the work laid out for this season, and one great object they had in view was to furnish a supply to the ranches at Bangor, Evansville and Wyandotte. The resident, Mr. Green, well said that it was the minees would be worked out, and the ranches would last a lifetime, and to look for his best and most lasting work. The company are doing as they should, which is a guarantee that the plan will be carried out.

NEW MILLS.—*Calaveras Chronicle*, Dec. 25: The new mill at the Mt. Tmolus mine is finished and the battery in motion. There is a large quantity of rich ore in the dumps, and any amount of it in sight in the mine. The stamps are kept running day and night.

MONTE CRISTO.—WORK COMMENCED.—Work has been recommenced upon the Monte Cristo mine, Mosquito, Glencoe district. The mine has passed into the hands of Mr. H. Longley, superintendent of Garland's mill, who intends to thoroughly develop it, and has the necessary means and facilities. Considerable rock has previously been taken from the Monte Cristo which paid remarkably well.

intelligence of large yields from operations in quartz in the Glencoe district. Garland's, the principal custom mill in that section, is kept in constant employment, and the results of crushings are so favorable as to stimulate the working of mines in the district into increased activity. Labor is being expended on a great number of ledges with very satisfactory results in general. The last run of Garland's mill was made on rock from the well known Rickman mine, located in the suburbs of the village of Mosquito. Twenty-nine tons of ore were put under the stamps, yielding an aggregate of \$700—about \$25 per ton. There is no limit to the quantity of rock in sight in the mine, that will pay equally as well as the last crushing.

feet deep; running levels in good ore. Mina Rica is down 290 feet. The south level is through the dyke which is the north boundary of a rich ore chute. Ore looks splendid. The ore is accumulating very fast on the dump, beside employing the 8-stamp mill of the Enterprise Consolidated company. A much larger mill will be needed at an early day. The Champion crushed 22,000 tons recently which yielded a triefe over \$3,000—\$136 per ton. Some fifty tons of ore on the dump now. Crushing. Shaft 170 feet deep. The mine cannot be bought at any price.

from the Beckman mine paid \$29 per ton. Other crushing were made by other parties and yielded between \$25 and \$35 per ton. The owners are very reticent. The old shaft of Hadlock's mine is being retimbered. Albers is taking out the ore near his residence. The

Valentine is still under the tender care of lawyers. The Glencoe Consolidated appears to be the center of attraction. Quite a number of men are prospecting in its immediate vicinity. Preparations are being made by the superintendent to work the mine extensively at an early day.

INYO.

THE DEFIANCE FURNACE.—Inyo Independent, Dec. 25: The Defiance furnace was started up again last Monday, but only ran till about eleven o'clock that morning, getting out thirty-four bars, when the pump gave out, rendering it necessary to shut down again till that could be put in working order; started up again on Tuesday night with a fair prospect of a continuous run of two or three months. The first seven hours after starting on the last heat fifty-one bars were run out and at the end of that time was ready to tap again, so it will be seen this bids fair to be the champion furnace of the country, as the mine, so far, undoubtedly is among mines.

THE FIRST SHIPMENT.—The Defiance company made their first shipment of six and a half tons of bullion last Monday. This was a portion run out the first three days prior to having to shut down the furnace to repair the break in the bottom.

NAPA.

A QUICKSILVER MINE AT YOUNTVILLE.—Napa Register, Dec. 25: There is a fair prospect that Yountville will become something of a mining locality. Prospecting has been going on for some months past about a mile west of Charles Hopper's place, and a tunnel has been put in 100 ft; but the most promising specimens have been found outside the tunnel. Some specimens have been found which are pronounced very rich by experts. We have been shown some of them by Mr. Lyman, who has just surveyed the claim for a United States patent, and we reckon the exports may be light in their opinion. The mine has been christened the Mountain View, and is owned by A. S. Roney, R. Simmons, Wm. Johnson and Chas. Hopper.

NEVADA.

MINING ITEMS.—Nevada Transcript, Dec. 24: We understand the Selby Hill mining company, which was recently incorporated, will commence work on Selby hill in a short time. The Gold Tunnel hoisting works, recently put up, are about ready for operations. The Gold Flat quartz mine, known as the Gold Run, is looking splendidly now. The mines at Blue Tent are at work; water is obtained from the South Yuba canal company's ditch, and from the new ditch run the past year by the Blue Tent Consolidated company; the latter company have as yet only run about 600 inches of water to Blue Tent this winter, fearing, as their ditches are new, to run it to its fullest capacity. On the ridge all the mines are at work, and a clean up in some of the best ones will soon take place, and the gold be turned loose upon the market. In Little York township all the companies are washing, and plenty of water can be had by all. Gold ought to begin to come in lively next month.

PROSPECT COMPANY.—Foothill Tidings, Dec. 25: Mr. Ambrose Powning informs us that everything in the shape of repairing old tunnels is now completed and that the mine is now in good working condition; that the ledge in the tunnel and stopes is of good size and has the appearance of hearing excellent pay rock. Mr. Powning has had charge of the work for the Prospect company for some time and he seems to feel sanguine that they have a splendid showing in the old Perseverance.

DOWNEY MINE.—Work on this mine has recently been commenced and we understand that the tunnel is to be pushed as fast as possible. We are glad to learn that our old friend Joseph Soper has charge.

PLACER.

IOWA HILL MINES.—Cor. Ditch Flat Forum, Dec. 25: Several of the leading mines in this section have been busy this month, pipping for some twenty days, quite an unusual thing of late years in December. The following is the list as far as I have heard:

The Occident or Kidder claim will wash about twenty days altogether, with eleven hands, eight white men and three Chinamen. This is one of the best fitted up claims in the county. The ground is all good, with suitable pressure and fall. This company have done excellent work so far, having washed an immense amount of dirt.

THE ENTERPRISE.—This company has also made excellent progress for the time they have washed. This claim is also well fitted up, and has good facilities for working.

THE FALLER CLAIM.—The same remarks apply to this company, they having washed more dirt this month than they did all last season.

THE MORNING STAR.—This crack claim was not ready to take advantage of the late rains. It is, however, in perfect order now and will commence when there is sufficient water. It uses 1,000 inches, with 500 ft pressure.

From other water supplies several more claims commenced work at the same time and will probably continue right along. The Homer and Dr. Carr, at Wisconsin hill, the Thrielar, at Iowa hill, and one or two I believe at Independence hill.

HYDRAULIC MINES.—Auburn Herald, Dec. 25: The hydraulic mines in the upper part of the county still continue active, and are making their exertions felt for good. The Auburn gravel mine continues piping away with marvelous effect and good prospects. The Gold

Run ditch and mining company commenced washing through their bedrock tunnel on the 17th inst., day and night. Everything works splendidly. The company have purchased 840 acres of land in Summit valley, and intend to convert it into a reservoir, and use the water in their mines at Gold run.

SAN LUIS OBISPO.

QUICKSILVER MINING.—San Luis Obispo Tribune, Dec. 25: The mining interests of the county are growing brighter with every month's development. There is not a remaining doubt as to the fact of there being one of the richest and most extensive quicksilver belts running through the entire length of the county that is to be found in any portion of the State. The development of these mines will greatly quicken every other industry in the county. At the present time there are probably 250 men at work in these mines, and the amount of money put in circulation through their earnings is already considerable; but let the number be increased to one or two thousands, as it will might be, then everybody would feel its influence. The Oceanic company, for months in succession, last summer, paid as high as \$10,000 a month for wages and material, which gave a great impetus to all classes of business in and about Cambria. The Ocean View mine has now employed 60 men, and must keep up as large a force until the works are all completed. With these facts before us it ceases to be a wonder that the northern end of the county is so rapidly improving.

SIERRA.

HOWLAND FLAT.—Correspondence Mountain Messenger, Dec. 25: The Wink-Eye company have recently struck gravel which prospects well. This ground is the frontage of the Hawk-Eye and Pittsburg claims, and has never before been worked. The owners are energetic and doubtless will succeed. Chittenden & Company are running their tunnel for hydraulic purposes with 8-hour shifts, and hope to be able to complete it early in the spring so as to make use of the extensive water works they have erected at great cost in various parts of the town. It is supposed that they will be richly rewarded, as it is well known that their ground is exceedingly rich. Cox & Co., also the Comet company, are working in large force at their respective hydraulic mines at Pine grove. Both claims have already been worked for a number of years and have paid largely, but with a long water season, as the present one is proving to be, the product of gold will no doubt appear simply terrific. Gourley, Thatcher & Co. are pushing things vigorously at the California, and if good judgment and energy avail anything, will be handsomely rewarded. Besides these claims there are others too numerous to mention.

As I write everything is moving along in its accustomed channel in this once celebrated mining camp. Water is plenty, and all the miners are very busily engaged, and judging from the quantity of ground washed off in the hydraulic claims, will no doubt in due time be handsomely rewarded. All the drifting claims are working fuller complements of men than usual, and it really looks as if this camp would, ere long, again enjoy some portion of its pristine glory. Every one at present is busily employed at something, principally mining, which speaks volumes for the energy and industry of the people. At the Empire eighty men are employed, and the rich gravel is being run out in large quantities and with more economy than ever before in the history of mining. The Virginia company are running their main tunnel ahead as fast as well trained muscle and giant powder will allow, and ere long still another rich bonanza will be added to the mining resources of Northern Sierra.

Nevada.

WASHOE DISTRICT.

CONS. VIRGINIA.—Daily yield, 650 tons of ore. It is with pleasure that we record the fact that this mine is again producing ore at the rate of \$1,800,000 per month. On the 26th of October last the company's hoisting works, machinery, ore houses and mill were a mass of smouldering, red hot ruins. In fifty days from that time all is replaced, stronger, better and more convenient than ever before. All the defects of the old machinery and works have been remedied, and the new, although erected in all the haste possible, does the required work to perfection. It hardly seems possible that such can be the case, but so it is and a whole community—in fact we may say the Pacific coast—rejoices that it is so. The lower levels of the mine are all in the most perfect repair, and were it possible to obtain them, more mills would be immediately added to those already employed in crushing the ore.

CALIFORNIA.—But little has been done on the lower levels during the past week, owing to the want of a dump in which to place the ore extracted while running the prospecting drifts. Sinking the O. & C. shaft is making excellent progress, the rock in the bottom blasting out well. It is now down 912 ft. Work will soon be resumed on the lower levels. The new 60-stamp mill will be ready to start up in a very short time, and will be an immense addition to the crushing power of the Comstock.

OPHIR.—The machinery, both pumping and hoisting, is all running finely, and the water is being steadily lowered in the shaft below the 1500-ft level. The erection of the new incline machinery is nearly completed, and everything in and about the works will soon be ready to resume the extraction of ore from the lower levels. A large force of mechanics and laborers

are employed on the works, and all the energy possible is being displayed in the advancement of the work.

BECKER.—Gold Hill News, Dec. 23: Daily yield, 450 tons of ore. The ore breasts are looking well and yielding the usual amount of good milling ore. The bullion yield promises to be fully equal this month to that of November, the returns showing a large increase in the amount of gold value in the pulp and bullion assays.

KOSSTUTH.—Sinking the winze in the ore vein below the 200-ft level, 600 feet south of the main shaft, is making excellent progress, the bottom in ore assaying from \$23 to \$35 per ton, and which appears to be steadily increasing in value as the winze descends. It is now down 71 ft. The main south drift on the 350-ft level is in a distance of 256 ft, the face in quartz and low grade ore. The ledge at this point is very solid and well defined, and the quartz of a solid character.

JULIA.—The 1600-ft station is completed, and a main drift is being driven toward the ledge with all possible energy, and very flattering prospects. The main southwest drift on the 1500 ft level is being rapidly driven forward, the face in fine ledge matter.

JUSTICE.—The main shaft has reached the 1000-ft level and a new level will shortly be opened to develop the mine at that depth. The drift north at the 800-ft level is running in fine looking vein matter, giving good assays, and should soon reach the main ore body developed in the level above.

SAVAGE.—The water has been drained to the 2200-ft level, so that work can be resumed on the lower levels in a day or two more.

GOULD & CURNY.—There is a considerable portion of the shaft that is in a very bad condition, and it is deemed best to repair it before the water is extracted and work is resumed again on the 1700-ft level. There is considerable water on the 1700-ft level, which will not probably be extracted until the repairing of the shaft is completed.

SIERRA NEVADA.—Sinking the main shaft is going steadily ahead, the bottom in good sinking ground. The main west drift on the 1000-ft level is pressed vigorously forward, the rock in the face being quite hard.

FLORIDA.—West drift at the 400-ft level going ahead, with fine ore indications in the face.

HALE & NOBSCROSS.—Retimbering the main shaft is completed, the guides in place in the shaft, and everything ready to start up at once as the breakage of the main shaft of the pumping engine, which occurred a couple of days ago, is repaired.

IMPERIAL-EMPIRE.—Daily yield, 50 tons of ore. The ore extracted continues of a good quality, and the ore breasts between the 1930 and 1850-ft levels continue to both look and yield well. There has been considerable improvement shown by the prospecting drifts on the 2000-ft level during the past week.

UTAH.—A large force of mechanics and laborers are employed in the erection of the main hoisting works building, which is now almost completed. The heavy stone foundation of the pumping engine is being rapidly repleased.

EUROPA.—The main west drift on the 320-ft level is steadily advancing, the face in soft ledge material of a very encouraging and promising character.

LADY BYRON.—The 500-ft station is completed and sinking the main shaft has been again resumed. The prospecting drifts on the 330-ft level are being steadily advanced.

LEO.—The main southwest drift, following the foot-wall of the ledge, is steadily advancing, the face of the drift in good ore. An east cross cut has also been started, the entire distance of which is also in good ore mixed with an occasional streak of porphyry.

BALTIMORE AND AMERICAN FLAT.—The main incline has reached the 1050-ft level, at which point a new station is being opened preparatory to cross-cutting and prospecting the ore vein at that point.

PROSPECT.—The new hoisting works are now in active operation, and sinking the shaft is resumed with renewed energy. Three shifts of men are putting it down at a lively rate, and the diamond drill is materially assisting. Everything is working splendidly.

SILVER CLOUD.—Work is about being resumed on the old Silver Cloud mine, which lies a short distance to the northwest of the Silver Hill. It is a very eligible and promising location, and good ore has been found in it in former workings.

SUTRO TUNNEL.—Very good progress is being made at present, the rock working favorably. Good streaks of quartz giving healthy assays in gold and silver are obtained, and being fairly within the broad Comstock mineral belt, every foot of progress promises developments of interest. Total length of tunnel to-day, 11,721 ft.

ORIGINAL GOLD HILL.—Daily yield, 20 tons, which is being reduced at the Hope mill. Pulp assays average \$33, and very gratifying results are looked for from the first clean-up, which is to be made shortly. The ore-breasts of the south ore-body at the 340-ft level are looking finely.

GLOBE CONSOLIDATED.—The north drift on the 350-ft level is showing some fine quartz and ore. Preparations for the erection of new and powerful pumping machinery are going steadily forward.

SILVER HILL.—The 4th station in the main shaft is completed, and a drift started to cut the ore vein, which is now in a distance of 33 ft, the face in fair running ground.

CROWN POINT.—Daily yield, 425 tons of ore. The ore breasts show no change whatever.

Sinking the winze below the 1500-ft level is making good progress, the bottom still in ore. The main south drift, on the 1500-ft level, is being steadily advanced without change.

SUCOON.—The strong flow of water struck last week caused a temporary suspension of the sinking of the main shaft for a few days. The water is again reduced so as to allow of a resumption of work at the bottom.

SULLIVAN.—The tunnel having arrived at a point immediately beneath the bottom of the shaft, a station is now being cut out for a raise to connect with the shaft. This raise will have to be 44 feet in extent, which, added to the present depth of the shaft, will make it just 117 ft from the surface to the track floor of the tunnel. When this is completed and the proposed new hoisting works in position, the sinking of the shaft will be resumed. The ore vein or fissure deposit of ledge matter developed by this tunnel and shaft is 180 feet wide between the walls, which are clearly defined.

LEVIATHAN.—Cross-cut No. 3 from the north drift at the 420-ft level is now twelve feet into the vein of rich ore reported last Saturday, and the face of the drift continues in the same, giving assays as high as \$340 to the ton.

BULLION.—Sinking the main incline is making splendid progress. An apraise is shortly to be commenced from the north drift on the 1700-ft level, to connect with the bottom of the incline for ventilation purposes.

OVERMAN.—The shaft has been drained of water, the timbers repaired, and everything put in good shape for resuming the sinking, which will be done in a very few days more.

CHOLLAR-POIOSI.—Daily yield, 60 tons of ore, the average assay value of which is \$28 per ton. There is no change in any of the ore stopes or breasts.

NEW YORK CONS.—Work is being actively pushed ahead at the various prospecting levels, with very encouraging results. At the 800-ft level very good looking streaks of quartz of small size are being passed through.

YELLOW JACKET.—The north and south drifts from the bottom of the winzes on the 1940-ft level are steadily advancing to complete a connection at that point.

ROCK ISLAND.—The prospecting drifts on the 650-ft level are also being steadily advanced, the ledge opening out finely.

BUCKETE.—Sinking the south winze below the 500-ft level is making good headway, the ledge gradually widening, and the prospects of pay ore are steadily increasing.

LADY WASHINGTON.—The shaft is being actively sunk 3 feet per day, with the bottom still in the very favorable vein material heretofore reported.

Arizona.

A ROAD TO BRANSHAW AND PECK DISTRICTS.—Arizona Miner, Dec. 17: The people here have been isolated from the outer world so long that it is hard to realize that we are about to be connected with the balance of mankind by rail, but it is true, nevertheless. Californians fooled themselves in many instances and thought it was only talk, that a railroad would be a long time in crossing the Sierras and Rocky mountains, but before they were aware it was accomplished and found many communities unprepared for it. What Prescott wants is a railroad passing through the country on or near the 35th parallel, which would pass to the north of us and compel the mines on the south to make this their depot of trade. This she may not get, and in that case she more than ever needs a wagon road to the mines to keep the trade from going the other way to a Southern railroad. The road already built to the Crook mill on the East Hassayampa is not first-class all the way, but it is susceptible of vast improvements, and from the mill to the Bully Bueno mine, we are told, by practical men, that a good road can be made at a moderate cost. From there on we are not posted as to the route, but money will build it, and should the county and village governments both go in debt to a large amount, it would be the best enterprise they could possibly engage in.

Utah.

RICH DISCOVERIES IN SOUTHERN UTAH.—Bounteous City correspondence Salt Lake Tribune: In addition to our climatic blessings, we have an abundance of rich silver mines, which your correspondent is now developing and bringing to the surface their rich chlorides and horn silver—all in sandstone, too. Prof. Maynard, our assayer, has carefully sampled some 10 tons of ore from the Tecumseh mine, which I am now shipping to your city. The assays are highly satisfactory, and will no doubt create a stir in mining circles, and will demonstrate a new phase in mining (in Utah at least), viz.: that rich silver ore can and does exist in sandstone. And why should it not as well in Utah as in South America and Sonora? Hundreds of miners have passed through this country, have seen the rich ores here, and because it was a sandstone country, and they had never seen silver mines in sandstone, they would rush on to Arizona and Nevada, leaving richer mines behind them than they could expect to find elsewhere. The developments here will remove to some extent the prejudices against a sandstone formation, for the silver and sandstone reefs of Southern Utah and Northern Arizona will soon be alive with the never contented prospector.

The artesian well Dr. Thornton is having bored on the ranch of Carr & Haggin, in Kern county, is now down to a depth of 420 feet, and without any indication of water.

The Llama and Alpaca.

Wegive on this page of the PRESS pictures of two ruminant animals which are agreeable and even attractive in appearance, are inoffensive in their habits and are useful to man.

The first, the llama, bears a strong resemblance to the camel, and is looked upon by naturalists as the representative of that animal on this hemisphere, being confined to South America. Their teeth are like those of the camel, but they have no humps upon their backs. The tail, which is not shown in our picture, is short and hairy; their toes are slender, the soles narrow and separated in front.

The animal which occupies the position of representative of its family in our illustration has a larger fleece than is found on the wild herds.

There are two distinct species found in South America—the *Llama vicuna* and the *Llama guanaco*. They both inhabit the Peruvian Alps, the Pampeas and the mountains of Chile, extending as far as the Straits of Magellan. The former animal, the vicuna, is principally found in the most elevated land and mountains of Bolivia and Chile. This species is quite wild, and is said to have defeated all attempts to domesticate it.

The guanaco is the characteristic quadruped of the plains of Patagonia, and is found in considerable numbers over the temperate parts of South America. They live in herds, but are said to be easily domesticated when once caught.

The wool of the llama is made into cords and a ske, and of these again are made various stuffs; and in Mexico the bones are converted into instruments for weaving the wool. But the European sheep is gradually taking the place of the llama, even in Peru.

The Alpaca.

The alpaca inhabits the more elevated ranges of South America, living almost on the borders of perpetual snow. The Peruvians keep vast flocks of them for their long, silky fleeces, which for instance rival that of the Angora goats. The "alpaca cloth," of the dry goods trade, is made of this material. It is principally used for woman's clothing; but it is now largely used for covering unwholesome. In texture it is finer and more durable than cotton, and is much cheaper than silk.

ALCOHOL IN GINGER BEER.—It will be startling and possibly painful intelligence to many of our "total abstinence" friends, that one of their favorite beverages, ginger-beer, is really a fermented liquor, and contains alcohol in proportions varying from two to five per cent. In a series of articles on "Modern Researches on Alcohol," now appearing in the *London Sanitary Record*, Dr. Bathurst Woodman says: "I should be very sorry to diminish the sale of ginger-beer, which I regard as one of the best of our summer beverages, containing, as it does, in almost all samples, either free citric or tartaric acid, or the almost equally beneficial bitartrate of potash. I have before me the recipes of several large makers, and take the first that comes to hand. It contains, besides ginger, tartaric and citric acids, 200 lbs. of sugar to 180 gallons of water. These ingredients are duly fermented, etc., and then bottled. Now, 200 lbs. of sugar (cane sugar) will produce in fermentation nearly 100 pints of alcohol; and, making all allowances for loss in yeast, by evaporation, in bottling, etc., it is quite plain that this liquor will contain about four per cent. of alcohol, and the result of actual experiment shows the same. The other recipes only differ in the amount of the saccharine substances, as regards the water, or the kind of sugar present, or the acid employed. This percentage of alcohol is, of course, about half the strength of most of the malt liquors in common use by the middle class of this country, but about equal to many of the cheaper ales, and to much of the beer drunk in Germany and other parts of the Continent."

THE INDUCED CURRENT.—"It appeared as if the current, on its first rush through the primary wire, sought a purchase in the secondary one, and, by a kind of kick, impelled backward through the latter an electric wave, which subsided as soon as the primary current was fully established."—*Tyndall*.

Lee District.

From J. R. Frink, superintendent of the Emigrant mining company, in the above district, we learn additional items of interest concerning the mines there. Lee district lies about fifteen miles north of Darwin, in a mineral belt of dolomite limestone about twelve miles in width, which is bounded on each side by a belt of quartzite. The dolomite formation is frequently overlapped with manganese lime rock, which latter is occasionally crossed by streaks of celadon, in which many cavities appear lined with beautiful crystallizations peculiar to such formations elsewhere. The uniform dip of the country rock is to the southward at a very slight angle of declination, but this is expected to change more to the perpendicular as depth is attained, where also the country rock will in all probability merge from limestone into porphyry, as has been proven by deep explorations in other mineral sections elsewhere. The ores of Lee district carry silver in the form of chlorides, black sulphurets and horn silver, with very little lead, copper, antimony or other base metals, and are unquestionably the easiest free milling ore yet found in California. The metal appears in the highest concentrated form, and is without doubt the richest ever discovered in this section, while the veins show croppings of extraordinary width and are very easily extracted.

The principal locations were made in February of this year, but much time has been taken in shipping ores for experimental tests to Germany, and the company working the principal mines has only of late got fully organized and prepared for operations. The mines

Mines at Howland's Flat.

A correspondent of the *Plumas National*, writing from Howland's flat, Sierra county, says: In its palmy days Howland flat was one of the liveliest mining towns in Sierra county. When the Pittsburg, Union, Down East and Monumental were in full blast, giving employment to hundreds of miners, there were flush times at Howland. Many thought those days would last forever. "Twas but an idle dream—bright while it lasted, but, alas, too short. When those claims were worked out, the unsettled, roving miner "folded his tent like the Arab, and silently stole away," to seek new scenes of pleasure, and hunt for pastures new. Then the greater portion of the town was destroyed by fire, as if some avenging Nemesis was determined that not a vestige of the once cozy little town should remain to mark where it once stood. Then Howland began to "go down." But "hope springs eternal in the human breast," and there were those who still believed that at no very distant day business would again be resumed, more new mines would be opened, and that fickle fortune would again deign to smile on their efforts. Those men, with every faith in its future, rebuilt their homes, and once more the town began to assume its wonted air of contentment and stability. Nor were they entirely to be disappointed. Their hopes of the good time coming were to be partially realized. The "open sesame" of capital, aided by energy and perseverance, came to the rescue, and new mines opened and developed. Foremost among these is the Empire mine, which to-day gives employment to nearly eighty men. The tunnel is

The Providence and Nevada Mines.

From a recent number of the *Nevada Transcript* we extract the following concerning these mines:

The present owners of the Providence mine, consisting of the Walrath Brothers, John Hunter and Col. Berry, came into possession, by purchase, four years ago. They have, during that time, been engaged in thoroughly prospecting and developing the mine. For purchase money, improvements and labor, their books show an expenditure of \$413,000, the greater part of which has been taken out of the mine while opening it. But little of the ground opened has been worked. It has been the plan of the owners to open the mine for future instead of present gain. Most of the rock worked by them has been taken out of the north side of the shaft, where the ledge averages from twelve to fifty feet in width. But during the past year the south side has been explored, and the ledge is found to be smaller and much richer. All the work done thus far on that side is what is called dead work.

The incline shaft is down 800 feet. On this level the shaft has been run seventy feet. On the 700-foot level the drift is in 260 feet, and the ledge is eight feet wide. On the 600-foot level the drift is in 500 feet, and the ledge four feet thick. On the 500 and 400-foot levels the drifts are in 245 feet; on the 300-foot 170 feet have been drifted; on the 200-foot 259 feet, and on the 100-foot 400 feet have been drifted. The winze on the 700-foot level is down fifty feet.

The 600 and 700-foot levels are connected by a winze which is 175 feet south of the incline. The winzes in the 500 and 600-foot levels are 245 feet from the incline. In short, the ledge for a depth of 800 feet on the south side, is ready for stopping, and for a distance of 500 feet, the point now reached with the longest drift, the rock is the best ever found in the mine. The ledge averages about six feet in thickness, and much of it is composed of fully ninety per cent. base metal. Prof. Price, who visited the mine recently, thought, judging by the weight of ordinary rock, that there are 25,000 tons of rock ready for stopping in sight. We believe double that quantity would be nearer correct.

The company have a fine mill of twenty stamps, with all the modern improvements for saving gold attached, besides extensive chlorination works, all of which they are going to abandon and have works for the Fryer process erected as soon as arrangements can be made.

The first work put up by Mr. Fryer will be upon the Providence, which will be between now and next May. Forty tons of the ore are now at the Fryer works for a test. We think it but justice here to state, that the present promising condition of the Providence is owing in a great measure to Mr. Thomas, the foreman. His services are appreciated by his employers, and they credit their success in mining to him. It will well repay any one to visit the mine and examine it thoroughly. It is, in our opinion the Cometock of California, and we think all who visit it will coincide with our opinion. The owners have displayed a spirit of enterprise and pluck worthy of a rich reward, and we are certain they have it in sight.

The Nevada or Soggs' mine, as it used to be called, is an extension on the north of the Providence. The mill and hoisting works are on the north side of Deer creek, opposite the works of the Providence. The ledge in the Nevada varies from three to sixteen feet in width and averages about six feet. There has been a great deal of work done on the mine, and large quantities of ore have been extracted, which paid well, but the mine has never been systematically developed as has its neighbor, the Providence, from the fact that the different owners have dared push ahead and take the chance of failure. We were shown some rock by Mr. William Berry, the superintendent, the other day, which is being taken out from the 200 foot level, that shows free gold in large quantities, and which pays \$80 to the ton. With a little outlay of capital and deep work, there is but little doubt the Nevada would prove a very valuable mine.

The British Admiralty has arranged for Capt. Allan Young to go to Smith's sound next year to communicate with the Arctic expedition.

The Los Angeles and Independence railroad will probably be extended to Anaheim.

LLAMA.

ALPACA.

owned by them embrace the Valentine, which is twenty feet in width, and crops out hold for a length of 3,000 feet. It courses like all the other veins yet found there, northeast by southwest, and dips to the north. The average assays from this mine were \$1,200 per ton in silver, which appears in the form of chlorides and sulphurets. The Cactus is an immense ledge which shows croppings sixty feet wide. Upon this an incline has been sunk forty feet in depth, and the ore produced is of the richest variety of horn silver and stetteldite, from which assays have been made as high as \$18,000 per ton in silver. This is a most extraordinary showing, but we are satisfied from specimens exhibited to us by Mr. Frink that the results are fully sustained by the appearance of the ore, the metallic luster of which is only excelled by the minted coin itself. Among the other locations of this class are the Centennial, Philadelphia and Capital, all of which show the same characteristics on the surface that were found in the Cactus, and all of which promise equally as fine prospects, which only require development to prove. The Mountain View is a distant claim, which carries ore of the copper-silver-glance variety, and upon it no work has yet been done. About thirty locations have so far been made in Lee district, and if a dozen of them prove to be of the same value as the Cactus the district will produce enough in five years' time to (in figurative language) pay off the National debt. In other words, we look for wonderful results to be obtained from Lee district.—*Coso Mining News*.

The fisheries at Mukilteo have all closed for the season. They did not prove as profitable as was expected, about 100 tons being the total catch.

WASHINGTON dispatches indicate the probability of an Indian war in the Northwest this winter.

MUCH trouble is experienced at present in procuring sailors at the ports on Puget sound.

a monument of engineering skill. After running over 3,000 feet, part of the way through hard blasting rock and still harder cement, they tapped the pay channel and the Empire was a success. From the beginning of the work until the first load of pay-grit was dumped in the washing shed, this enterprise cost nearly \$8,000. Nor was the company, under the able and efficient management of the superintendent, Mr. J. P. De Noon, satisfied until all the appliances for washing, flumes, pipes, etc., were neatly and conveniently arranged. In fact, the Empire is to-day the model mine of Sierra county, and so far as the richness of the gravel is concerned, it pays more, man for man and load for load, than the Bald Mountain at Forest City. At present Mr. Geo. Reobley is day-foreman, and Robert Patterson night-foreman. Both are good, practical miners, and well liked by the boys. Another company, the Virginia, is running for the same channel, but it will be some time before they get into pay.

Down to the Grove there are two companies at work in hydraulic claims, the Comet and Cox Brothers. In the spring the Last Chance company propose to take a chance. Those companies are making their mines "ante," and as the indications are good for a first-rate water season, we shall hear of some large "clean-ups."

COPPER IN INYO.—The *Inyo Independent* says: Among other important enterprises likely soon to add to the fame and wealth of Inyo county is the proposed workings of the immense copper ledge in Ubebebe district, to which we have frequently alluded heretofore. This ledge is a monster; its ores being carbonate, no difficulty is apprehended as to their profitable reduction by a furnace similar to that used for silver lead. Mr. Belschw, who has purchased the property from Messrs. Hunter and Porter, intends to locate his furnace in the edge of Salinas valley, some twenty miles east of Cerro Gordo, and within easy reach of the mines, this work to be undertaken on or before early spring.

USEFUL INFORMATION.

WILL HUMAN SALIVA KILL SNAKES?—The Merietta (Ga.) Journal was told by a gentleman the other day that human spittle was as deadly to poisonous snakes as their bites were deadly to man. He says while picking up a bundle of straw and trash under his arm, while cleaning a field, a ground rattlesnake, four feet long, crawled out from it and fell to the ground at his feet. He at once placed his heel upon the head of the snake and spit in its mouth. Shortly afterward the snake showed symptoms of inactivity and sickness, and he picked it up by its tail and carried it to the house and showed it to his wife, telling her he had spit in its mouth and that it was poisoned. At the expiration of fifteen minutes the snake was dead. To further experiment he came across a blowing adder (snake), which ejected from its mouth a yellowish liquid. He caught it and spit in its mouth, and it died. He caught another blowing, and it refused to open its mouth. He spit upon a stick and rubbed the spittle upon the adder's nose, and it died. Afterward he came across a black snake, regarded as not poisonous, and he caught it and spit in its mouth. Instead of the spittle killing the black snake, as it did the poisonous reptiles, it only made it stupidly sick, from which it recovered. This conclusively shows that poisonous snakes have as much to fear from the spittle of man as man has to fear from their bites.

HOW FAR WILL BEES GO FOR HONEY?—This is a question which has never been satisfactorily answered. A bee-keeper once tried the old experiment of dusting his bees with flour as they left the hive, then rode to a health seven miles away, where he discovered his white bees most busily collecting honey; however, this experiment cannot be relied upon, for the simple reason that pollen, with which bees are often completely covered, bears a general resemblance to flour, and might be mistaken in color when the bees are on the wing. We think they seldom venture more than three miles from home, for we have known them to be in a starving condition when another apiary four miles away was flourishing, and gathering stores rapidly. It has in recent years been proved by Italian hybrids that queens have met with drones which were known to be at least three miles away, but this will scarcely apply to worker bees flitting about from flower to flower; they must become weary before they are three or four miles from their home.

GOLD.—The New York Mercantile Journal says that in view of the small amount of gold in the world in proportion to the increased amount of commerce, the efforts to regulate exchanges and pay balances in gold is as fruitless as to endeavor to quench the thirst of an elephant from a tea saucer. Within the past year over \$60,000,000 worth of gold have been shipped from the port of New York, and about half as much more from San Francisco. This country is sending to Europe annually about \$250,000,000 in gold for interest on national and state bonds held there, and for the balance against us for gew-gaws and delicacies we do not need, and for the traveling and living expenses of our snobs who go there and spend their money because this country is too much of a democracy for them.

COLORING OAK WOOD.—According to Niedling, a beautiful orange-yellow tone, much admired in a chest at the Vienna Exhibition, may be imparted to oak wood by rubbing it in a warm room with a certain mixture until it acquires a dull polish, and then coating it after an hour with a thin polish, and repeating the coating of polish to improve the depth and brilliancy of the tone. The ingredients for the rubbing mixture are about three ounces of tallow, three-fourths ounce of wax and one pint of oil of turpentine, mixed by heating together and stirring.—*English Mechanic.*

BURNING OF A TIRE.—One of those accidents, not very common but still well known and understood, of the bursting of a locomotive tire, recently occurred near Oakes station, Penn., on the Perkiomen railroad. It was a steel tire, and the accident occurred while the train was in slow motion, just nearing the station. The tire first struck the foot board, near where the engineer stood, broke it into a thousand splinters, and next bounded thirty feet into the air, and came down in a field more than a hundred yards distant.

THE USE OF IODINE.—The objection which many persons urge against using tincture of iodine on the skin is, that the stain is ineradicable, except after considerable time. If a few drops of carbolic acid be added to the tincture, says a medical journal, it will not stain; moreover, the tincture itself is more efficacious.

FOR SMOKING GRATES, ETC.—A screen or blower of wire gauze, from thirty-six to forty wires to the inch, placed in front of range or stove fires, or grate, will prevent, it is said, smoke coming into the room when the chimney fails to draw well.

A POTATO PARSER is among the latest inventions, which, it is claimed, will pare perfectly, long, crooked, unevenly shaped potatoes with a great saving of time, and a large saving of the potato over ordinary hand paring. It also pares turnips or apples.

A PROPOSED INSECT COMMISSION.—A memorial was submitted to the meeting and approved, which addresses Congress with relation to the establishment of a national insect commission. The document states that the damage done by the noxious insects in the United States amounts to \$300,000,000 per annum. The subscribers propose either the reorganization of the Department of Agriculture, under the control of the highest scientific authorities, or the appointment of a commission of five persons, to wit: Three entomologists, one chemist, and one botanist, eminent in their respective branches of science, to be chosen by the council of the National Academy of Science, and approved by the secretary of the treasury, with salaries adequate for the responsible work. The duty of this commission would be to investigate the causes which affect injuriously agricultural interests, and to suggest the best means of diminishing the losses. The results of such investigations should be embodied in brief reports, containing practical instructions and made accessible at a small price; or the results should be made useful, by personal education, to every farmer in the country.

AN ALLOY OF COPPER ADHERENT TO GLASS.—An alloy of copper which will adhere to glass or porcelain is made by mixing from twenty to thirty parts of copper in powder, (obtained by the reduction of the oxide by hydrogen or by the precipitation of the sulphate by zinc) with sulphuric acid and then with seven parts of mercury. The mixture is triturated and mingled with care. The acid is removed by washing in hot water, and the mass allowed to dry. At the end of ten or twelve hours, the latter becomes quite hard and susceptible to a fine polish. On heating it softens, but on cooling does not contract. This alloy may also be used for joining delicate objects which will not withstand very high temperatures.

LAMP CHIMNEYS.—Most people in cleaning lamp chimneys use a brush made of bristles twisted into a wire, or a rag on the point of scissors. Both of these are bad; for without great care the wire or scissors will scratch the glass as a diamond does, which under the expansive power of heat soon breaks, as all scratched glass will. If you want a neat little thing that costs nothing, and will save half your glass, tie a piece of soft sponge the size of your chimney to a pine stick.

TO DEODORIZE COCONUT OIL.—Mix with 1.32 parts freshly prepared bone black and 1.32 parts calcined magnesia, digest for three days, shaking frequently; let stand till clear and filter.

GOOD HEALTH.

Origin of the Water Cure.

The water cure, or hydropathy, owes its origin to the fertility of invention of a Silesian peasant, Vincenz Priessnitz. Having at the age of thirteen sprained his wrist, young Priessnitz intuitively applied it to the pump; and afterward, to continue the relief thus obtained, he bound upon it a wet bandage. Retaining this as it became dry, he reduced the inflammation, but excited a rash on the surface of the part. Soon after, having crushed his thumb, he again applied the bandage, and the pain once more subsided, but the rash reappeared. He inferred that the rash indicated an impure blood; and this conclusion was strengthened by the result of experiments which he was induced to try upon injuries and ulcers in the case of some of his neighbors, since the rash in some instances appeared after the treatment, and in others did not. Thus he was led to frame for himself a humoral pathology of all diseases, and a doctrine of the elimination of morbid matter by "crisis." According to this view, the cure of disease is to be effected by favoring the activity of those organs through which the purification of the system is carried on, and, through a regulated and pure dietary and correct regimen, preventing further morbid accumulations. In his nineteenth year, being run over by a cart, Priessnitz had some ribs broken and received severe bruises; on learning that the physicians pronounced his case hopeless, he tore off their bandages, and recovered under the renewed application of the wet bandage, and replaced his ribs by inflating the lungs while pressing the abdomen against a window sill. This incident confirmed the idea and initiated the practice of the water cure.

A PRACTICAL TEST.—A correspondent sends us the following, which shows the importance of a close examination of our health columns: "A subscriber not at all interested in your 'split bean' remedy when she read it, soon found occasion to do something for a rough nail puncture which was very painful; and was perfectly astonished at the speedy relief, quick and painless healing. Her faith is now strong in that remedy." This fact illustrates a whole class of experience, and shows the utility of knowledge and facts in store for the moment when some emergency will prove their value. Some do not read the health column because they are not then needing such information, but when they do need that knowledge they have not time or opportunity; similarly excused as was the Arkansas farmer for not roofing his house.

The Effect of a Diseased Liver.

A healthy liver secretes each day about two and a half pounds of bile, which contains a great amount of waste material taken from the blood. When the liver becomes torpid or congested, it fails to eliminate this vast amount of noxious substance, which, therefore, remains to poison the blood and be conveyed to every part of the system. What must be the condition of the blood when it is receiving and retaining each day two and a half pounds of poison? Nature tries to work off this poison through other channels and organs—the kidneys, lungs, skin, etc., but these organs become overtaxed in performing this labor, in addition to their natural functions, and cannot long withstand the pressure, but become variously diseased.

The brain, which is the great electrical center of all vitality, is nudly stimulated by the unhealthy blood which passes to it from the heart, and it fails to perform its office healthfully. Hence the symptoms of bile poisoning, which are dullness, headache, incapacity to keep the mind on any subject, impairment of memory, dizziness, sleepy or nervous feelings, gloomy forebodings and irritability of temper. The blood itself being diseased, as it forms the sweat upon the surface of the skin, is so irritating and poisonous that it produces discolored brown spots, pimples, blotches and eruptions, sores, boils, carbuncles and scrofulous tumors. The stomach, bowels and other organs spoken of, cannot escape becoming affected, sooner or later, and costiveness, piles, dropsy, dyspepsia, diarrhoea, female weakness and many other forms of chronic disease are among the necessary results.

Tape Worms.

The origin of tape worms is the eating of measly pork, which has not been sufficiently cooked to destroy the germ. It may also be communicated to beef by the knife of the butcher, should he cut pork and beef with the same knife. The germ adheres to the interior of the human intestines, soon becomes the head of the tape worm, and then the links grow, each of which eats and digests independently of the head.

To remove it, a large oose of Rochelle salts is given at night; at ten o'clock in the morning a dose is given made of one-half ounce of bark of pomegranate root, one-half drachm pumpkin seed, one drachm ethereal extract of male fern, one-half drachm powdered ergot, two drachms powdered gum arabic, and two drops of croton oil. The pomegranate bark and pumpkin seed are to be thoroughly bruised and, with the ergot, boiled in eight ounces of water for fifteen minutes, then strained through a coarse cloth. The croton oil is first well rubbed up with the acacia and extract of male fern, and then formed into an emulsion with the decoction. In each case the tape worm will be expelled alive and entire within two hours.

The above prescription is from the *Druggist's Circular*, and is similar to the old established method; but a recent publication informs us that where this has failed, the tape worm was effectively driven out by means of diluted carbolic acid, which is a poison for all small animals and inferior forms of life.

NEW MODE OF ADMINISTERING RAW MEAT.—M. Laborde, in a French medical journal, recommends the following method for the preparation of raw meat: Make a not very thick broth of tapioca, and let it cool. The meat, finely scraped, is diluted with a quantity of cold soup, with which it is thoroughly mixed until it looks like tomato soup. The tapioca is then turned in, little by little, with constant stirring. A homogeneous liquid is thus obtained, in which, when properly made, the meat is so thoroughly disguised that the person eating it does not suspect its presence. The preparation has been often given under the name of "medicinal porridge of tapioca," and has proved very acceptable to the patients.

USEFUL APPLICATION OF THE DOG'S STRONG DIGESTION.—The daily papers announce the following item: "A Hartford man recently got a piece of tough meat lodged in the lower part of the esophagus, making breathing difficult and threatening inflammation, and was treated by Dr. Ellsworth of that city, who killed a number of dogs, and with the gastric juice of their stomach coatings, succeeded in dissolving the piece in the course of the day." As no animal has a stronger digestion for bones and tough meat than the dog, its gastric juice being very powerful, it was a happy idea of Dr. Ellsworth to employ this for the solution of the difficulty.

DYSPEPTIC HUNGER.—If a man is hungry within an hour, more or less, after a regular meal, he is dyspeptic beyond question, and it shows that the stomach is not able to work what he has eaten, so as to get nourishment out of it; but to eat again, and thus impose more work, when it could do nothing for what had already been eaten, is an absurdity; and yet all dyspeptics who eat when they are hungry do this very thing, and thus aggravate and protract their sufferings.

SICK HEADACHE.—Two teaspoonfuls of finely powdered charcoal, drank in a half tumbler of water, will often give relief to the sick headache when caused, as in most cases it is, by a superabundance of acid in the stomach.

DOMESTIC ECONOMY.

How to Carve and Help at Table.

It is considered an accomplishment for a person to know how to carve well at his or her own table. It is not proper to stand in carving. The carving knife should be sharp and thin.

To carve fowls (which should always be laid with the breast uppermost,) place the fork in the breast and take off the wings and the legs without turning the fowl; then cut out the merry thought, cut slices from the breast, take out the collar bone, cut off the side pieces and then cut the carcass in two. Divide the joints in the leg of a turkey.

In carving a sirloin cut thin slices from the side next to yon (it must be put on the dish with the tenderloin underneath), then turn it end out from the tenderloin. Help the guests to both kinds.

In carving a leg of mutton or ham, begin by cutting across the middle to the bone. Cut a tongue across, and not lengthwise, and help from the middle.

Carve a forequarter of lamb by separating the shoulder from the ribs, and then divide the ribs.

To carve a loin of veal begin at the smaller end and separate the ribs. Help each one to a piece of kidney and its fat. Carve pork and mutton in the same way.

To carve a fillet of veal begin at the top, and help to the stuffing with each slice. In a breast of veal separate the breast end brisket, and then cut them up, asking which part is preferred.

In carving a pig it is customary to divide it and take off the head before it comes to the table, as to many persons the head is revolting. Cut off the limbs and divide the ribs.

In carving venison make a deep incision down to the bone to let out the juices, and turn the broad end toward you, cutting deep, in thin slices.

For a saddle of venison cut from the tail toward the other end, on each side, in thin slices. Warm plates are very necessary with venison end mutton, and in winter are desirable for all meats.—*National Agriculturist.*

TO MAKE DUTCH CHEESE.—The domestic article made of sour milk, often known as "Dutch cheese" or "pot cheese," is prepared in the following way: "Set the vessel containing the sour milk on the stove over a kettle of water, and let it heat up slowly till the milk thickens and the whey is partly separated. As soon as the curd becomes firm enough to handle (before it becomes hard and the whey all separated) it is removed and suspended in a cloth or perforated tin long enough to drain off the whey and cool. If for domestic use, it is broken up, and about half as much sweet cream added as originally belonged to the milk, and salted and otherwise seasoned to taste with some aromatic, if desired, and either made into hand cakes or packed away in a vessel for use. If for market, the curd is drained and broken up, and salted and seasoned with a little pepper or caraway seed, and a little butter added, so that the particles of curd will adhere, and then molded by hand into four-ounce cakes or cheeses and placed at once upon the market, where a ready sale is usually found at remunerative prices. The original German practice was to place the hand cheese as above made between layers of straw, and let them lie till cured, so as to develop some of the Limburger flavor. But the general practice in America is to use them while fresh.

BREADEN TOMATOES.—Cut off the tops of twelve ripe tomatoes, scoop out the seeds, set them in a pan with one gill of salad, and fill with the following preparation: One-half pint of mushrooms, one handful of parsley, four shallots, two ounces of fat bacon and two ounces of lean ham, all chopped fine and seasoned with a little thyme, pepper and salt; heat this mixture over the fire five minutes, take it off and stir in the yolks of four eggs; fill the tomatoes, cover them well with browned bread crumbs, cook in a hot oven fifteen minutes and serve with or without Italian sauce.

DRESSED MUTTON.—To have it as it should be, the dish must be lined with mashed potatoes, the mutton nicely minced and properly seasoned, placed in a dish, a little stock added, and then covered over with mashed potatoes roughed with a fork, and placed before the fire till the little dish assumes the appearance of a nicely baked hedgehog. The hotter served the better relished, provided it has only been allowed to simmer and not to boil.

"What shall I cook?" is a short but vexatious question, engrossing more serious thought, probably, than any other one question in the world. Many a good and industrious wife can be greatly relieved, and many a farmer's table blessed his sight and appetite, by providing now for a good garden. If you love your wife and daughters do not put it off for money making enterprises on the farm.

STEWED POTATOES.—Take cold boiled potatoes, pare them and cut in thin slices; to a pint of milk, when scalding hot, stir in a tablespoonful of butter and flour, rubbed together; salt to taste; add the yolk of one egg and some parsley chopped fine. When well mixed, throw in the potatoes, shaking carefully without a spoon to avoid breaking. Let them stew for a few moments and serve.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Safety Apparatus, by A. and L. Donayrouze; Scenery on the Yellowstone, Page 1. Mining Terms; Wear of Wire Rope; The Gould & Curry Mine; Notices of Recent Patents; 8. Ball's Sweeping Dredge; American Progress; Gravel Mining on "The Ridge," 9. Book Notices; The Ophir Mine; Patents and Inventions; General News Items, 12.

ILLUSTRATIONS.—Safety Apparatus for Miners, Second Canon of the Yellowstone, 1. American Progress, 9.

CORRESPONDENCE.—Krom vs. Rittinger, 2.

MECHANICAL PROGRESS.—Engines for Steep Grades; Street Railroad Transit; The Use of Petroleum in Drilling; The Danko Furnace; A New System of Prison Construction; New Mode of Making Bolts' Nuts; New Material for Building; How to Apply a Leather Covering to an Iron Pulley; Indestructible Trains, 3.

SCIENTIFIC PROGRESS.—The New Element—Gallium; The Germination of Seeds in Ice; The Genesis of Atoms; A Gas Shadow; How Far Will Bodies Sink in the Ocean? Sir Isaac Newton's Experiments; More Paleozoic Frogs; Conduction of Heat by Building Materials, 3.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 4.

MINING SUMMARY from various counties in California, Nevada, Arizona and Utah, 4-5-12.

USEFUL INFORMATION.—Will Human Salt Kill Snakes? How Far Will Bees go for Honey? Gold; Coloring Oak Wood; Bursting of a Tire; The Use of Iodine; For Smoking Grates, Etc.; A Proposed Insect Commission; An Alloy of Copper Adherent to Glass; Lamp Chimneys; To Deodorize Coconut Oil, 7.

DOMESTIC ECONOMY.—How to Carve and Help a Table Knife; Butter Cheese; Breaded Tomatoes; Dressed Mutton; Stewed Potatoes, 7.

GOOD HEALTH.—Origin of the Water Cure; A Practical Test; The Effect of a Diseased Liver; Tape Worms; New Mode of Administering Raw Meat; Useful Application of the Dog's Strong Digestion; Dyspeptic Hunger; Sick Headache, 7.

MISCELLANEOUS.—The Kossuth Mine and Machinery; Improved Method of Teaching the Alphabet; Opening for Mining Enterprises; Quartz Mining in Montana; Important Outlook for Gas Fuel, 2. The Llana and Alpaca; Alcohol in Ginger Beer; The Induced Current; Lee District; Mines at Howland's Flat; Copper in Inyo; The Providence and Nevada Mines, 6. Another Bonanza Suit; Chinese Miners—How they Work; Education of the Flea, 10.

Stitched and Trimmed for the Good of Our Patrons.

Our readers will receive this first number of the Press for 1876 stitched and trimmed, ready for reading upon whichever page they choose first, without let or hindrance. This feature will be one of the improvements promised in our sheet for the New Year which we hope our readers will fully appreciate. It will be a real convenience to them at least fifty-two times during 1876. The present age calls for time saving expedients. This is one of them. It trims up the avenues to our advertising as well as reading pages, and thereby is an important benefit to our advertisers as well as subscribers. It nearly doubles the value of our advertising pages, but we shall not raise accordingly on our rates; neither shall we allow new advertisers to override our reading columns if we have ever so great a rush.

Large folding and pasting machines are expensive. In the principal Eastern cities, a dozen or more journals are often printed in a single job office. In such cases, one folding and pasting machine may do the work of all at a comparatively small cost to each, but on this coast we can have no such co-operative opportunities, and we have to accomplish the new work exhibited to our readers to-day single handed.

If this first week every copy is not finished as perfectly as desired, we will try and do the work better with each succeeding issue. Although somewhat expensive to the publishers, we believe the improvement will be well appreciated by our readers, whom we invite assist us in extending the circulation of the Press.

Mining Terms.

We wish that some intelligent person familiar with the Comstock would compile a vocabulary of mining terms used in that section, as they differ in some respects from those used in other places, many being peculiar to the district. In many cases, terms which elsewhere mean one thing, mean something quite different on the Comstock, their adoption having been made by common custom. Numerous instances of this might be cited, but a single one of recent occurrence will be sufficient.

In the annual report of the Ophir mine the superintendent says: "The prospecting on the lowest level (1700 foot) discloses in the west cross-cuts a great disturbance of the west wall of the lode, and the eastern cross-cuts, as far as they have penetrated, have passed through 'horses' or masses of west country, and entered more favorable formation with 'stratums' of low grade ore following out east, which evinces a 'heave' or pushing of the ore vein, and gives hopes of discovery of ore deposits on this level further east."

We did not understand the superintendent's expression of "passing through horses or masses of west country," and asked several old miners familiar with the Comstock who couldn't understand it either; so we have examined what works of reference we have at hand, to see the correct definition of both 'horse' and 'heave,' used, as we think, incorrectly in the above paragraph.

In Foster & Whitney's glossary of mining and metallurgical terms, in their government "Report on the Geology and Topography of Lake Superior Land District," (1850), a "heave" is defined as "the horizontal dislocation which occurs when one lode is intersected by another having a different direction."

Von Cotta's "Treatise on Ore Deposits" defines the term heave as "that sometimes applied to horizontal dislocation which occurs when one lode is intersected by another; a slide is a vertical dislocation of a lode."

Page's "Hand Book of Geological Terms" defines heave as "the displacement of a vein or bed by the intersection of another vein or fault. When the intersected vein is thrown up it is said to be a 'heave,' and when thrown down a 'slide.'" Heave and slide are thus merely relative terms according to the position from which they are viewed.

In the "Student's Manual of Geology," by J. Beete Jukes, "horse" is a term commonly applied by vein miners to any large, detached mass of rock occurring in a vein or lying between two branches of a vein. In Foster & Whitney's glossary, it is defined as "the dead ground between two branches of a lode."

Wear of Wire Rope.

The directors of the Clay street hill railroad recently removed the old wire rope which has been in use for some two years and substituted a new one. The road runs up Clay street hill, and the cars are propelled by an endless wire rope passing up one side of the street and down the other, underground. The engine furnishing the power is at the upper end of the line. The old rope was 7,000 feet long, three inches in circumference, and made of 114 steel wires of No. 16 gauge. It was put in use August 22d, 1873, and was in use two years, three months and twenty days when removed. It was made to work seventeen hours a day while running. During this time it carried 3,300,000 passengers.

A few deductions showing the amount of work obtained from this rope will be of interest. The 3,300,000 at an average of 150 pounds apiece would give 495,000,000 pounds. Eight cars go up twenty-five times a day for 840 days, giving 705,600,000 pounds. Adding the weight of the cars to passengers it gives 1,200,600,000 pounds, or 600,300 tons, raised 307 feet vertically in a distance of 3,300 feet in 840 days, working seventeen hours a day. The result is, we get 1,200,600,000 pounds raised 307 feet in 856,800 minutes. This rope traveled 64,260 miles, or more than equal to two and a half times the distance around the globe.

While this rope was running it stretched about one per cent., or 70 feet on the 7,000. It was reduced in circumference about seven-thirty-seconds of an inch. The consumption of coal by the engine to perform this work was about 1,500 pounds of Wellington screenings per day, at \$9 per ton. From experiments made at the station it was found that it took six pounds of steam to keep the rope running (unloaded) after it was started. It took twelve pounds to overcome the inertia and friction. The cylinder of the engine is twelve by twenty-four inches. This ropeshow is a pretty good record and shows what wire rope will do. It was made by A. S. Hallidie, of this city, from imported steel wire. The changing of the ropes took thirteen hours. The rope shows little signs of wear and would probably last a year or more longer with safety, but the directors thought best to take all precautions and change in time.

The new rope is 7,000 feet long and weighs 10,800 pounds. It is the same that was on exhibition at the late Mechanics' Institute Fair. It is made of fine steel wire, hardened and tempered, No. 16 gauge. There are 114 steel wires and nineteen soft iron wires for the heart. The rope is three inches in circumference, and was made at Hallidie's factory, in this city.

As a matter of record we may also mention the data obtained for a rope in use at the Crown Point mine on the Comstock. Mr. Hallidie has a statement up to the 6th of November. The steel rope was set at work August 1st, 1874, on the incline. The rope is 2,650 feet long, 6 1/4 inches in circumference and weighs 17,237 pounds. Up to the date mentioned it had worked 10,928 hours, and hoisted 209,592 tons. It runs at a speed of 670 feet per minute. Total weight of each lift 34,000 lbs.; vertical distance 1,500 feet. This gives 209,592 tons raised 1,500 feet in 10,928 hours. The rope is still at work and in good order. The record of these ropes speaks well for our California manufacturers.

The Gould & Curry Mine.

The annual meeting of the Gould & Curry mine was held this week. Mr. James G. Fair, the superintendent, in his annual report says that in the previous annual report he recommended that two additional compartments of the main shaft be sunk from the 1200-foot to the 1500-foot level, and that during the year the work was done, doubling their hoisting capacity as well as bettering the ventilation of the mine. Work on the shaft between the 1500-ft level and the surface had been continuous throughout the twelvemonth. Notwithstanding this work the shaft is now in bad condition and extremely dangerous—the swelling ground crushes in the timbers and is a constant source of delay and expense, and Mr. Fair recommends a stoppage of work for a short time and a substantial retimbering of the four compartments of the shaft, from the 1500-foot to the fifth levels. This can be done at the same time work in the mine is carried on, but, in the superintendent's opinion, the cost by this method would be doubled and the work would not be as substantial as it would be were all other work stopped. The year has shown a material increase in the flow of water in the mine, three-quarters of it coming from the east side of the shaft over the 1500-ft level. All of the eight-inch pumps have been removed within the year, and a twelve-inch pump substituted, but even with this increased capacity he was unable to keep the mine free from water below the 1600-foot level. The moving of the timbers in the shaft displaces pumps and pump-rods, causing stoppages constantly and the accumulation of water, which can only be remedied by a thorough retimbering of the shaft. On the 1700-foot level the main drift has been extended to the northern boundary and connected with the Best & Belcher joint winze sunk from the 1500-ft level, which secured a good ventilation. The east drift on this level has been run east from the incline 1,033 feet to the east wall of the vein, but as it showed strong indications of water, and as the pumps were already working to their full capacity, it was deemed best not to cut into the vein. No cross-cuts have yet been made on this level, and its value, therefore, has not been ascertained. The formations passed through by lateral drifts look favorable and assay from \$5 to \$20 per ton, but all the work done so far is outside the ore vein. The winze sunk 182 feet below the 1700-ft level, designed to connect with the 2000-ft level of the Savage, is now filled with water. The 1500-ft level has been thoroughly developed by cross-cuts in all parts, but no ore of value has been discovered. Much work has been done on the levels above in prospecting new levels and repairing and extending old ones, but all have failed to disclose ore of value. It is evident, says the superintendent in concluding his report, that the company must look to the 1700 ft level and further depths for the production of ores. Buildings, engines and machinery are in excellent order, and there are good supplies of timber and materials on hand for the winter.

The following is a synopsis of the secretary's report: Receipts during the fiscal year amounted to \$339,399—of which \$97,648 were from an assessment, \$222,749 from the sale of 12,000 shares of stock, and \$18,466 from various other sources. Disbursements amounted to \$328,377, leaving as cash on hand at the close \$11,022. Of the disbursements \$280,348 was for labor, \$4,090 for a sluice tunnel, \$3,503 for legal expenses, \$1,174 for exchange, \$22,972 for general expenses, \$3,766 for interest, \$1,752 for taxes, and \$29.84 for minor items.

The following Trustees were elected: Edward Barron (President), George Congdon (Vice President), James G. Fair (Superintendent), James C. Flood, William S. Lyle, Robert Sherwood and R. H. Follis.

A NEW VOLUME.—With this number the MINING AND SCIENTIFIC PRESS commences volume XXII, and while wishing our many readers a very Happy New Year, we take occasion at the same time to suggest that it is a very proper time to renew subscriptions about to expire. We have endeavored during the past year to make as interesting and valuable a paper to miners, mechanics and other industrial readers as possible, and flatter ourselves that we have succeeded very well. The Press has now attained a ripe age and its usefulness has increased with its years. No miner or manufacturer can afford to be without the representative industrial publication of the Pacific coast. We shall in the future, as in the past, look out for everything of interest or benefit to our patrons, and only need from them their co-operation and support to continue to maintain a paper worthy of the interests it represents.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

FRICTION PULLEY.—Alfred Swiggle, S. F. This invention relates to a novel construction of a friction pulley, and consists of a pulley mounted to turn loosely upon a shaft, which has a disk, moving longitudinally upon a feather, so that by means of a sort of double knee lever, or toggle, the face of the disk can be moved closely against the side of the pulley, and by its friction cause the two to move together as one. These knee levers are operated by a sliding clutch, and are made to stand at a small angle between the disk and the bar against which they act, so that when the strain comes upon the pulley it will tend to bind the flange closer to it. This provides a frictional device for driving loose pulleys.

REVERSIBLE PINION FOR WATCHES.—Frank E. Smith, S. F. This is an improved method of attaching the center wheel pinions of watches to the arbors or shafts of the center wheels, in order to allow the pinion to turn in a reverse direction, and relieve the strain upon the mechanism of the watch in case the mainspring should break. This arrangement is very simple and can be cheaply applied, while it does not encumber the pinion with outside attachments, which are at the same time complicated and unsightly in a watch.

IMPROVEMENT IN RAILWAY CARS.—Joseph Bolt, Benicia, Cal. This invention is intended particularly for the transportation of troops and second class passengers on railways, but may be also used for first class passenger cars. The improvements consist in certain arrangements which make the cars convenient for day and night travel, so that provision is made for sleeping at night as well as for seats by day. The inventor takes the ordinary seats for four persons. In order to accommodate these persons in a recumbent position at night it will be necessary to convert the surface into a continuous surface or bed for two, while the space above will be occupied by another mattress or bed for two more persons. In the special device used for this purpose by Mr. Bolt the seat frames are arranged to slide a short distance forward or back. To the edges of each seat nearest the ends of the sections are hinged extension pieces. These pieces are folded beneath the seat in the day time, but at night are allowed to rest on a supporting ledge at the ends of the sections, forming a continuation of the seat, and serve as a part of the bed. The arms of the seats are pivoted, so that they may be reversed in the usual manner. The links connecting the seat back with the arms of the seat are made double, so as to be extended or shortened, and by this arrangement the inventor is able to lay the back of one seat horizontally, so as to fill the space between that seat and the one behind it. The back of the other seat is not disturbed, but serves as a head board for the bed. The upper berth is hung upon hooks, so as to be swung up close to the roof during the day. The improvements made by Mr. Bolt also include racks for guns, etc. These racks are arranged in a series of four, attached to the side of the car above each two seats of the section. They are made so as to suit any size of gun that may be carried by the troops.

MAP OF CALIFORNIA.—Whitney's geological survey map of California has been revised by Messrs. Hoffman & Craven, and issued in a perfect manner for the benefit of such of our citizens as wish a correct map of its size and at a moderate cost. Mr. E. M. Sleater, the agent, is selling the last of the limited edition printed at the reduced price of \$3.50, instead of \$5, for copies mounted on cloth and rollers. Since the first edition was issued, the counties of San Benito and Modoc have been organized; Klamath has been extinguished, and the lines of Butte, Colusa, Los Angeles, Inyo, San Bernardino, Tulare, Fresno, Santa Barbara, San Luis Obispo, Monterey, Siskiyou, Humboldt, Nevada and Sierra have been changed. The extensions of the railroad to Bakersfield, Spadra and San Fernando, and the routes of the road to Monterey, Santa Cruz, Marin and Amador are shown. New towns are also put down. The State of Nevada is included, and additions are there made. The scale of this, as of the first edition, is eighteen miles to one inch.

BALL'S DREDGE.—Mr. John A. Ball has a communication in another column giving a brief history of his experiments with his dredging apparatus, which was recently described in these columns. Mr. Ball is a painstaking inventor who has overcome many serious obstacles heretofore and is hard at work removing others. His machine is well worthy of a critical examination by those interested in mechanical contrivances, as well as by those for whose benefit it is to work. There are many novel points in its construction, and as far as we can see it does the work it is intended to do very well. Mr. Ball is an active, intelligent man, enthusiastic on the subject to which he has directed his attention, and is worthy of success, which he will, no doubt, ultimately achieve.

Ball's Sweeping Dredge.

Many of the readers of your valuable paper, I believe, will read with interest a statement from myself, relative to my enterprise, namely, the Ball sweeping dredge. I desire to place before the public some outline of what I am aiming to accomplish, which is no small matter to the interests of our State and country.

In the summer of 1862 I crossed the plains and settled in Nevada county, where, under adverse circumstances, I accomplished but little, until I came to Oakland about three years ago. While living in Nevada county I traveled some in the great valleys of this State and became awakened to the importance of a general system of irrigation. Having seen what irrigation had done for the poor desert land of the Mormons, I saw how much more favorable were the conditions as to the soil, climate and supply of water for irrigating the great valleys of California, if a grand systematic plan could be had to provide water for all the land possible. At that time I predicted that sooner or

capals and building reservoirs, therefore waded to see that if I could successfully introduce steam machinery for doing such work, I would do much to advance the project, also better my own circumstances.

About ten years ago I invented the main principles of my improvements in dredging and excavating machinery, and during all these years, although in a helpless condition, I have been centering all my energies to accomplish the one object, namely, to get into practical use steam machinery for digging canals. But while thus engaged, an opportunity was presented which enabled me to experiment by attaching my improvements to a dredging machine first. I have made many radical changes from any other dredging machine yet in use, and still I find opportunity for improvements. The results thus far attained, I mean in regard to dredging into scows, then towing to deep water and dumping, assure me that no other machinery now in use can successfully compete with mine. I think the dumping practice is wrong, and believe the taking of the material dredged from under water on the shore is a great necessity; and that by adding to my improvements already made, I shall successfully provide the machinery for that purpose

especially those interested in excavating or dredging, to examine the machine now at work along the water front, San Francisco, where can be seen whether I have any reasonable grounds for supposing that such machinery would dig the canals successfully, with speed and at a cheaper rate than by any other means.

The work that has been done for some time past has averaged over 1,500 cubic yards per day of six and a half hours.

About one-half of the time the dredger lies idle for want of the scows being towed away as fast as they are filled, as no one tug can tow the scows away as fast as they are filled. The average time of filling each scow of 105 cubic yards is less than twelve minutes. I am prepared now to do dredging for less than forty per cent. of the prices heretofore existing in this State, and I feel sure that when I have more fully perfected my machinery I shall be able to dig and transfer earth from one place to another, in nearly every case of requirement, for one-tenth of the present cost by the means heretofore used, and also to facilitate such work in proportion that steam power does in the many other uses, as in manufacturing, etc. Therefore, I am hoping to assist in the more rapid development of our country, by aiding

material struggles in which we have triumphed, and the foes of civilization which have been put to flight. Upon the right of the picture the light of a good day of enlightenment shines upon our favored coast. It is the light which we now enjoy.

To us in this day the glorious facts which are suggested by this engraving seem grand accomplishments. But there is a future still beyond, and those who, in that day of even greater things, shall look upon these marks of progress which so delight our thought, may think them small indeed. But thus it is ever-onward.

Gravel Mining on "the Ridge."

The Ridge, as the gravel range of Nevada and Sierra counties is called, is now yielding largely in gold. From Gold Lake, Sierra City, Downieville, Forest City, Monte Cristo, Eureka, Brandy Flat, Indian Hill, Comptonville, Moore's and Woolsey's flats, North Bloomfield, Columbia Hill, Cherokee, San Juan, Sweetland, French Corral and Nevada City to Grass Valley, are all now furnishing their share of bullion. Many

AMERICAN PROGRESS.

later the subject would become a political issue, and a State general system of canals for irrigation, transportation and water for the cities that were to grow, would be accomplished. I would like to dwell more particularly on this point, with reference to some of the causes that have thus far retarded the State government from advancing the subject of its greatest interest—the allowing individuals and incorporated companies to get possession of the water rights and large tracts of land through the various ways of intrigue in which they successfully have operated, thereby placing as it were a complete nightmare on the prosperity of our State, shutting out the poor man from opportunities to till the soil, and thus prolonging the time when the State should be under a high state of cultivation.

Perhaps I am more expectant than many others who have given much thought to the subject. I feel assured that most men in predicting the future progress in the development of the resources of the Pacific States, come far short of what will be seen by those who live twenty years from this date—that a general system, utilizing all the water flowing from the mountains to the great valleys, for irrigation, transportation, manufacturing and other purposes, is the most important feature in the future of our State. Being thus awakened to the importance of the subject, and the certainty that such a scheme would be accomplished, I saw there would be millions of cubic yards of earth to remove in digging the many miles of

I feel sure that my improvements in machinery have already been a benefit to the State by causing a great reduction in the price of dredging, and I hope they will soon prove to be of great importance to the commercial, farming, and many other interests of our country, especially on this coast. In such assurances, I am sustained by many who are well known to the public to possess a high degree of intelligence, and who occupy positions giving them that experience which best qualifies them to judge correctly with regard to the future progress of our State and country. I have not yet had a test to prove the value of my inventions adapted to land excavation, which I believe of more value than the same used for dredging. Nearly two years ago I succeeded in making a temporary experiment by attaching some of my improvements to an old dredge, which proved by its work done on the Oakland bar that there was value in my improvement; but those proofs did not materially strengthen me to raise means to carry forth the enterprise.

This was because of an unreasonable opposition by parties who would have done much better for their own interest and mine, also, had they been willing to deal with me honorably. After being for a time handicapped, I at last succeeded in finding a man able and willing to enter into a fair bargain to share with me to build a complete dredging machine. This machine is not yet as perfect as I am sure I can make it; but I earnestly invite all who feel an interest in the progress of the invention, and

in the construction of the canals of which I have spoken.

I am thankful to a kind Providence that I have been able to advance my enterprise to the extent I have, and with so great success. I am encouraged to persevere regardless of the opposition or hindrances that I may yet have to encounter. I am gratified to see the growing sentiment in favor of a general system of irrigation, and that there is a probability of some definite action in its favor at the present session of our State Legislature.

JOHN A. BALL.

Oakland, Dec. 30th, 1875.

American Progress.

The beautiful typical picture which we present this week is appropriate to the beginning of the Centennial year. It will lead our readers to step for a moment and look back upon the way along which our nation has advanced within their own memories, and will suggest also a thought forward to the lights which lie before us. It will bring vividly to mind the lines of our advancement and the obstacles we have overcome. The leading figure has in her right hand the secret of our advancement; the book being a fitting symbol of intelligence, civilization and education. From her left hand fall the wires over which thought flashes from ocean to ocean. Beneath her is spread the

of the individual companies' operations would require a long article to do any justice to their importance or magnitude. Every time one visits a mining camp there are some improvements to note in machinery or methods of manipulating—multiplying under-currents, changing their styles of rifles, etc., and when you converse with the inventors of these new methods, you find they know why the one arrangement is preferable to the other, both theoretically and practically.

At the North Bloomfield gravel mining company can be seen a very interesting invention of the superintendent, H. C. Perkins, for turning or changing the direction of the water discharge pipe. By the old appliances it sometimes required two or three men to change the direction of the pipe, but now a child four years old can easily change the direction of the discharge pipe of the largest chief or monitor. To effect this the device is simple and philosophical. An independent and outside nozzle of about ten inches in length is secured to the discharge end of the pipe, by a universal joint, in such a manner that the false nozzle may, by means of a small rod, be tipped slightly across the current of the escaping stream, and thereby cause the pipe to move in the direction or side where the obstruction is. When the direction is changed as far as desired, the false nozzle is adjusted in the line of the true nozzle, and being larger, the stream is not affected by it. This invention will probably be secured at an early day by letters patent.

Another Bonanza Suit.

Solomon Weill has brought suit in the Third district court against the Consolidated Virginia mining company. The complaint alleges that in 1861 the White & Murphy company was organized to work the White & Murphy claim on the Comstock lode, bounded on the north by the Kinney claim and on the south by the Dick Sides claim. The capital stock was \$126,000, divided into 849 shares. The Consolidated Virginia mining company was organized in June, 1867, with \$2,320,000 capital stock, in 1,160 shares, to work to the north of the Dick Sides claim, embracing 500 feet on the lode—the White & Murphy claim; the Kinney claim, embracing 50 feet; the Central Number Two, embracing 100 feet, and lying north of and adjacent to the Kinney claim; the California claim, embracing 300 feet, lying immediately north of and adjoining the Central Number Two. The capital stock of the Consolidated Virginia company has been increased to \$5,400,000, divided into 540,000 shares. The White & Murphy company duly conveyed its title in the White & Murphy ground to the Consolidated Virginia company at the time of the organization of the latter company. The plaintiff at the time of the transfer owned 38½ shares of the stock of the White & Murphy company, being one-half of 77½ shares, which stood on the books in the name of one Harris Jacobs. The complaint avers that the Consolidated Virginia company agreed with the White & Murphy company that the stockholders thereof should be entitled to own and hold of the capital stock of the Consolidated Virginia one share for each four shares of the White & Murphy company. Weill, therefore, claims that he is the owner of 7,365 shares of the stock of the Consolidated Virginia, and demands judgment that the company be required to issue a certificate for the same.

A similar complaint to the foregoing was filed in the same court against the company by Harris Jacobs, to establish his claim to a corresponding number of shares acquired in the same manner.

Chinese Miners—How They Work.

The Oroville (Butte county) *Mercury* says: On the bluff, just outside the town limits, and on the lot formerly occupied by Henry White, the buildings have been taken down, the vines and fruit trees pulled up, and in their stead is a steam pump, owned and worked by a lot of Chinamen. Numerous shafts, thirty, forty and fifty feet deep, are sunk into the earth, and the engine is kept at work all day pumping out the water, while gangs of men are at work in the ground, digging up the earth. A windlass is over each shaft, which is provided with a long rope and two tubs, with which to draw up the rich dirt. This is emptied into wheelbarrows and taken to a sort of reservoir, where the water is four or five inches in depth, and emptied in. In this water stand a number of Chinamen, with shovels, putting the wet dirt into the old-fashioned rocker. At the side of the rocker stands a patriarchal fellow, rocking away as carefully as does the mother her child. At night each rocker is cleaned up and the head man takes charge of the gold. For they would much sooner trust an American with their gold than one of their own number. Thus, day after day they work on, with less rest and comfort than the Southern slaves ever had. During all this cold weather not one of them ever wore anything upon his feet, except the "head men." Near each crew of men one can see a tea-urn, filled with cold tea, of which each workman takes a swallow now and then. Some of them, however, have a stronger decoction, called China gin, made at F. A. Mathews' ranch, one drink of which would cause a white man to hunt a blacksmith to screw down the top of his head. Altogether they seem quite happy and contented.

EDUCATION OF THE FLEA.—Mr. Bertolotto, the well known educator of the flea, is now in New York exhibiting his curious success in this line. The insects he employs appear to be the species of flea common to dogs. The first lesson, he says, is to put the insects in a small circular glass box, where, by jumping and knocking their heads against the glass for a day or two, the idea is finally beaten into them that it is useless to jump; and during the remainder of their natural lives, to wit, about eight months, they are content to crawl. Having corrected their intellects in regard to jumping, the instructor now fastens a delicate pair of wire nippers to the middle part of the flea's body; to the nippers any desired form of miniature vehicle, such as a wheelbarrow, a car, a wagon, etc., is attached, and the flea thus harnessed trots away with the load, to the great amusement of the lookers-on. The professor harnesses his insect pupils into a great variety of other positions, and makes them perform many curious duties, such as the operation of a fortune telling wheel, orchestra playing, racing, etc. They are allowed to feed twice daily upon the instructor's arm. It remains for Mr. Darwin and his co-seekers to determine what effect this system of insect education is likely to have upon the habits and development of future broods.

ALASKA, with its area of 570,000 square miles, will, if annexed to Washington Territory, make a very respectable sized county—about as large as Oregon, California, Arizona and New Mexico combined. With this addition, the Territory of Washington will have an area of 640,000 square miles.

At a Stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant.—In equity.

DECREED.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER, Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines. It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practiced in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

F. MANSELL & CO.,
SIGN PAINTERS,

423 PINE STREET,
(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors, Gents' Furnish'g G'ds,
Bootmakers, Furniture Dealers,
Hatters, Jewelers,
Hotels, Piano Fortes,
Wine Merchants, Etc., Etc.

54 BUSHELS OF CORN AN HOUR.

HARRISON'S

LIGHT VERTICAL BURR MILLS

BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, Vt., write July 15th: "We have been running two of your Light Vertical Corn Mills for the past 6 months with remarkable results, and have ground over 5,000 bushels of corn into No. 1 meal in that time, running the mill night and day, as we run our saw-mill in the day time. We have often ground in the 20-inch mill (which weighs about 600 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 34,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILLS, we shall take great pleasure in giving the results."

New Books.

THE PACIFIC COAST DIRECTORY, FOR 1876, has just appeared, this being the third year of its publication. It contains the name and post-office address of each merchant, manufacturer, and professional, residing in California, Oregon, Nevada, Washington, Idaho, Montana, Utah, Arizona, Alaska and British Columbia; also, a gazetteer of the counties, cities and towns, with the Federal, State and municipal offices attached thereto, and an exhibit of the resources of the Pacific coast. The work was compiled by Henry G. Langley, with his usual accuracy. It shows that a great deal of labor and expense has been incurred in collecting the material, since a large amount of information, from different sources, has been collected. The general description of California is very full and well compiled, giving a great deal of useful information. A list of railroads of the Pacific coast is given, with the routes and details of operation; a list of the quartz mills in California is given, with the name, cost, date of erection, number of stamps, etc. There is also a table of the quicksilver furnaces, with similar details; also, a table of the grist mills, with location, name, run of stone, power and cost, owner, etc. The same details are given of the saw mills. There are tables giving the number of libraries, with the volumes; list of newspapers and periodicals, populations of towns and counties; meteorological tables, and these for the different States and Territories. The book is really a valuable one for reference, and should be in everybody's hand. We shall make some interesting extracts from it at a future time.

MARK TWAIN'S humor is so generally appreciated and well known that any criticisms on "MARK TWAIN'S SKETCHES," (Roman & Co.) now published in complete form, would be superfluous. The book is well printed and bound, and is profusely illustrated with appropriate engravings. In addition to the old there are several new sketches, all brimful of Mark's peculiar humor. The book is handsomely bound, and would make a good holiday gift. The "Jumping Frog restored to the English tongue after martyrdom in the French," is as funny as the original story; and the "Memorandum Croup" sketch will be read by the married men with great interest, as it is treated of something in their remembrance. The "Sketches" can be taken up with pleasure during idle hours, and will bear repeated reading.

VICK'S FLORAL GUIDE.—We have received a copy of Vick's Floral Guide for 1876. It is an excellent publication, and is praiseworthy in many ways. It is replete with new facts concerning flowers and vegetables, and with instructions concerning their culture. Among the most interesting topics we notice an illustrated essay on mushroom growing, and another concerning berry-bearing plants which are used for decorations. Mr. Vick also gives an entertaining account of his recent visit to the Yosemite valley. The Floral Guide is published at twenty-five cents a year, and may be obtained by addressing James Vick, Rochester, New York.

CROFT'S GUIDE.—The typical illustration, "Westward Ho," which we print elsewhere this week, was designed for Croft's Guide for the Overland Trip. Mr. Croft's publication has met a large sale, and is the standard work in its class. It is purchasable from the train boys on the overland trains.

The Ophir Mine.

The annual report of the Ophir silver mining company is quite interesting and exhaustive, being accompanied with elaborate and well arranged tables and statements, showing details of all operations. During a part of this year, while opening new parts of the mine for future operations, new bodies of ore were found, paying well for reducing, and indications of other bodies have been disclosed. It is a matter of remark and interest that the Ophir is the only one of so many mines on the Comstock that had rich ore when first opened, and also found it with depth. This fact is of great importance, and offers hopes for many other mines.

The Ophir has been in operation for fifteen years, and now stands more prominently out, perhaps, than ever before. The production of bullion last year exceeds any previous one by over \$300,000, and but for the very serious interruption by fire, would have been increased to more than half a million dollars. The greatest previous production was in 1863—\$1,514,222.21—while this year it was \$1,817,187.19. From the table of bullion production which we append, it will be seen that for the past five months the ore has steadily increased in richness, running up from \$26.94 per ton to \$58.54 per ton, giving a fair basis for reasonable anticipations when the ore body shall again be reached.

When the Ophir was first opened, we recollect that some four tons of ore were taken from the croppings and sent to this city, which worked about \$5,000 per ton. The mine yielded and paid well for some time, but for several years past has paid no dividends. The

past year it has been self-sustaining, and would probably have paid dividends had it not been for the fire. As before remarked, it is important to note that the Ophir is the only one of the Comstock mines which has struck rich ore in any quantity both on the surface and at a great depth.

With this encouraging outlook, and in the midst of the company's greatest prosperity, upon the eve of resuming dividends, the dire disaster of fire overwhelmed it, laying its valuable and costly works in ruins, and stopping all operations for a month or more. Works as fine as had ever been erected on any mine, had recently been completed at a cost of over \$300,000, and the mine was in fine working condition in all its parts when the fire of October 26th occurred, sweeping off everything consumable, and irreparably damaging a great portion of the machinery. In just one month's time, however, by the untiring zeal and superior management of Superintendent Curtis, the buildings and works were replaced and again ready for hoisting. But after overcoming these serious difficulties they had yet to meet another disaster in finding the mine flooded up to the 1500-foot station, with more or less slight caves from drift facings, by which there will probably be lost much good ore by being mixed with worthless debris and rendering it unfit for milling. Before the fire it was expected that dividends would be paid by the beginning of the new year, but the great damage both by fire and water defers that to the indefinite future.

During the fiscal year, up to October 26th, the date of destruction of the works, 51,322 tons of ore were extracted, which, with 105 tons on hand at mills, at the commencement of year, yielded bullion amounting to \$1,817,187.19. The superintendent, Mr. Samuel T. Curtis, reports that during the year a large amount of prospecting has been done on the different levels, several air channels and winzes constructed, making the mine very cool and producing beneficial results in the increased facilities afforded the miners to work. The main vertical shaft has been sunk 125 feet, and the upper 400 feet retimbered, before and after the fire. A large station has been cut out on the 1600 level, preparatory to sinking incline shaft.

"The prospecting on the lowest level (1700 feet) discloses in the west cross-cuts a great disturbance of the west wall of the lode, and the eastern cross-cuts as far as they have penetrated, have passed through 'horses' or masses of west country, and entered more favorable formation with stratum of low grade ore following out east, which evinces a 'heave' or pushing of the ore vein, and gives hopes of discovery of ore deposits on this level further east."

"The ore bodies on the 1300 level show strength in raising, and the angle of raise proves that the long abandoned 1100 and 700-foot stations were not prospected far enough east, by from three to five hundred feet, if the ore bodies discovered on the 1300 level raise that high. Two months ago, I started a drift southeast from the 1100 station to test this theory, the last work done in which showed signs of a favorable formation."

Very large and substantial buildings were erected, and powerful and first class pumping engine and gears, incline engines and gear and tapered reel; to the shaft of the latter were connected two hydraulic engines worked by the water of the mine, under a pressure of 400 feet head. Those hydraulic engines give an auxiliary power of 268-horse while hoisting, and in lowering form a water balance counteracting weight of giraffe and steel cable, and are calculated to save considerable fuel.

A large ore house was constructed alongside of railroad, to which the ore is to be raised by water elevator, using the same power as the hydraulic engines. This system of elevating the ore forty-seven feet to railroad was adopted after careful consideration and perfect surveys for line of switch from railroad, which it was found would cost \$45,000 for the only practicable route, whereas the hydraulic machinery cost but about \$6,000. Two air compressors were also put up, and compressed air introduced into the mine, which has proved serviceable and economical, running Burleigh drills, air fans and hoisting ore from winzes. All this powerful machinery and first-class buildings covering an area of 39,522 square feet, and forming one of the most thorough works on the lead were just completed when the terrible Virginia fire swept the works away, and with the one thousand cords of wood and nearly 400,000 feet of running timber. The heat was so intense that railroad car wheels were melted in the open air alongside the works. When the fire abated it was found that the heavy timbers of the galleys frame, partially burned, had fallen down the shaft, breaking a portion of the platform that had been put in to protect the shaft and mine, and the fire was working its way down the shaft. For thirty-six hours a stream of water was played down the shaft until the safety of the shaft and mine was assured.

On the day after the fire competent men were dispatched to the lumber yards of Carson and Dutch Flat, Cal., to procure and ship timbers. Machinery was telegraphed for; the new double reel hoisting engine and cables just completed for the combination shaft of the Chollar Potosi, Hale & Norcross and Savage, secured, and through the heaviest storms Virginia has seen for years, the old engine foundations were torn out and new ones to suit combination engine constructed, work was prosecuted without cessation, supplies hauled a considerable distance

on account of destruction of railroad tunnel and bridges, the works rebuilt and work through shaft resumed November 25th, being inside of thirty days from time of destruction.

While the reconstruction of works was going on, a donkey engine, furnished through the kindness of the Phil. Sheridan mining company, was put in place, with which they were enabled to re timber the shaft where it had been burned to a depth of 400 feet from surface, besides hoisting considerable of the water making on the 700 feet level of mine.

The buildings rebuilt have been made much larger, and more complete and convenient than formerly. Most of the machinery which passed through the fire has been made available, especially the new incline and pumping engines, which suffered but little damage. From the two hoisting engines of vertical shaft, which received most damage, one good engine has been completed at little cost, and foundations are being laid to put in place for hoisting power for a new compartment of shaft, which, when completed, will give three hoisting compartments and one pumping compartment, and give hoisting capacity of fully 1,000 tons per day. A considerable amount has been expended for new machinery and buildings during the year, but the amount covers the first construction of the extensive buildings and heavy, first-class machinery, and very nearly the amount of whole cost of reconstruction.

The total receipts for the year have been, according to the secretary's report, \$2,096,310.24, of which \$1,817,187 was from bullion, and from an assessment, \$201,600. Cash on hand, Dec. 15th, 1875, \$211,254. In the expenditures are the following items: Engines and machinery for Buck's shaft, \$177,968; labor on Buck's shaft, \$329,136; wood and timbers on shaft, \$104,042; wire cables, \$21,916; labor on the machinery at shaft, \$54,408; foundry work, \$24,588.

The cost of extracting the ore from the mine was \$256,614; cost of prospecting (labor, material, constructing air channels, sinking main shaft and underground repairs), \$299,017.03; machinery and buildings prior to November 1st, \$302,105.25; since November 1st, \$108,344.97; general expenses, \$21,266.43; milling ore (including \$132,476.50 paid on account of ore worked prior to December 1st, 1874) \$773,798.50. Total cost at mine, \$1,761,146.18.

We append a table of ores worked, assay values, bullion returns, etc.

Months.	Ore Worked.	Assay Value.	Yield.	Assay Value of Bullion.	Total.	Value of Total Yield.

November.....	1,841	61.83	58.54	42,170.61	38,422.11	80,592.72
Averages and Totals.....	51,322	\$35.83	\$26.10	\$1,817,187.19	\$590,938.31	\$2,408,125.50

The above table is quite instructive, and may be considered a representative statement of work on the Comstock. The yield per cent. of assay value, it may be seen, varies greatly. The gradual increase of value of ore up to the time of the fire can be seen. Another feature worthy of notice is the large proportion of gold, which is nearly equal to the silver, in the ore. Many people suppose that a very large proportion of the yield is silver, and that very little gold comes from the Comstock, but reference to this table will show that the idea is a mistaken one.

DEADMAN'S canon, Los Angeles county, is being surveyed for the purpose of discovering a better pass than Soledad.

The greatest coal of Mendocino county is a railroad from Ukiah to Cloverdale.

The spring crop of coughs and colds is heavy, and will ripen into a terrible harvest of disease and death, unless rooted out with the standard antidote, HALE'S HONEY OF HOREHOUND AND TAR. Pike's Toothache Drops cure in one minute.

General News Items.

Mining and Other Companies.

Cherokee Flat Blue Gravel Company—

Location of principal place of business, San Francisco, Cal.

Location of works, Cherokee Flat, Butte County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-eighth day of December, 1875, an assessment, No. 25, of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, room 13, Safe Deposit Building, No. 323 Montgomery street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid on the third day of January, 1876, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Saturday, the nineteenth day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. H. BOGART, Secretary.

Office, room 13, No. 323 Montgomery street, San Francisco, Cal.

Owyhee Water and Gravel Mining Company.

Location of principal place of business, San Francisco, Cal.

Location of mines, Elko County, Nev.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, (No. 1) levied on the first day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names. No. Certificate. No. Shares. Amt.

M A Baldwin	37	100	\$30 00
M A Baldwin	43	7400	2220 00
B Lando, trustee	64	10000	3000 00
B Lando, trustee	60	50	15 00
O H Lagrange, trustee	39	100	30 00

PACIFIC

Rolling Mill Company,

SAN FRANCISCO, CAL.

Established for the Manufacture of

RAILROAD AND OTHER IRON

Every Variety of Shafting.

Embracing ALL SIZES of
Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames.

-ALSO-

HAMMERED IRON

Of every description and size.

Orders addressed to PACIFIC ROLLING MILL COMPANY, P. O. box 2032, San Francisco, Cal., will receive prompt attention.
The highest price paid for Scrap Iron.

SHEET IRON PIPE.
THE

Risdon Iron and Locomotive Works

Corner Howard and Beale Streets,

Are prepared to make SHEET IRON AND ASPHALTUM PIPE, of any size and for any pressure, and contract to lay the same where wanted, guaranteeing a perfect working pipe with the least amount of material.

Standard size of railroad Car Wheels, with special patterns for Mining Cars. These small wheels are made of the best Car Wheel Iron, properly chilled, and can be fitted up with the improved axle and box—introduced by this company, and guaranteed to outlast any other wheels made in this State.

All kinds of Machinery made and repaired.

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

- 1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
- 2d. The best Concentrator I have ever known—(the concentrated stuff only containing 6 per cent. of sand).
- 3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
- 4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past, have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,

JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, April 27, 1872.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.

MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$3,500 per month more than with the blankets and buddles formerly in use.

O. O. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—Dear Sir: Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.

E. R. BURKE, Superintendent.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

1v29-3m

CAST STEEL SHOE & DIE CO., Room 4, Academy Building, S. F.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

WITH LATE IMPORTANT IMPROVEMENTS.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new illustrated Catalogue. TREADWELL & CO.

VOLUME XXXII
Number 2.

The Kohler Reduction Works.

We paid a visit this week to the Kohler reduction works, which are situated about six miles from Oakland, and are connected on one side with the Central Pacific railroad, and on the other with the bay, so as to secure an easy transportation of ores and materials by land and water. The works are on a large scale, and when fully complete will involve the expenditure of a large amount of capital. When in complete working order they will be able to reduce fifty tons per day. Up to the present time over \$50,000 have been expended on the buildings, which, however, are by no means complete.

The buildings are substantially built and conveniently arranged. They comprise a frame building, 60x1,000 feet, well built, divided into business, assayer's office and laboratory, leaving ample room for the manufacture of concentrators. A one-story brick building, 26x60, with an artesian well in it capable of throwing forty-five gallons a minute, a 60-horse power engine and suitable boiler in place, with all necessary appurtenances. So far about 600,000 bricks have been laid on the works, including with the above-named brick buildings a chimney twenty-five feet square at the base, and roasting, smelting and refining furnaces.

The chimney of the works, now 75 feet high, will be 165 feet when completed. The smelting furnaces consist, at the lower part of their circumference, of a strong double wall of cast iron, and between these two walls a regulated stream of water is circulating, so as to prevent the iron walls from being destroyed by a too great heat; the upper part of the smelting furnaces are made of fire-bricks, and the escaping fumes of lead, antimony, arsenic and other volatile substances are forced to travel a long way before they reach the chimney, and to deposit in those underground chambers, and partly at the bottom of the high chimney, everything valuable that would otherwise be carried out in the open air and lost. They are constructed on plans by Mr. R. J. Kohler, the superintendent and inventor of the process. The furnace is arranged to put through 50 tons per day of 24 hours. It was started up for the first time this week on ore from the Reforma mine, Mexico. Mr. Kohler says he tapped it in one hour after firing up, which is pretty quick work. It works quickly and keeps from five to six men busy to keep it running. A four-foot blower furnishes the blast to the furnace and refining furnaces. The engine runs at 50 revolutions, and the blower at 2,500 revolutions per minute. The blast feed pipe is very large, fourteen inches in diameter, and the blower fills it to its utmost capacity.

The proprietors are unwilling to make the patents of the process public, but Mr. Kohler informs us that it is merely in the kind of flux he uses for various kinds of ores. He has had great experience in metallurgical operations of this character, and is firmly impressed that this process is the best that can be devised for rebellious ores. He proposes to save the sulphur, arsenic and antimony with fluxes. He charges the furnace every eight minutes with 500 pounds of ore, and keeps it running lively all the time. The ore at present being worked is very rebellious.

The refining works are not yet completed, so the bullion is base. The refinery furnaces are partially completed, and are the same as Mr. Kohler has used successfully in Mexico. He says he will be able to turn out his bullion 997 fine, and pass through five tons a day.

They have also partially completed a large roasting furnace to roast certain ores before smelting, and also to extract the antimony, arsenic and sulphur. Mr. Kohler says by this method he can work the ore to much better advantage, as it will save labor and cost in refining. The works are as yet by no means complete, as the company have had some financial embarrassments to contend with, which they hope soon to remedy. As soon as they are in complete working order we will have a more detailed description of the works.

TUCSON, Arizona, is building up rapidly. Among other structures recently erected is a school house, costing \$10,000.

Ventilating Pipes and Floodways in Warehouses and Buildings.

We learn from recent issues of the *Scientific American* that a Mr. John H. Morrell, an enterprising capitalist of New York city, who lately invested about a million dollars in the erection of a six-story warehouse with large safe deposit vaults attached, has recently invented a new system for ventilation and cleansing drain pipes in buildings; also an improved floodway for warehouses. The latter is intended to enply a quick discharge from the

ceptacles, the rain water which falls on the roof is collected and conducted to the various traps or closets, or water may be supplied to said reservoir by a pump or other convenient means. If the house is closed and empty, the system of pipes will serve as ventilators; and when a fall of rain occurs they will then serve to fill the traps, thus supplying the water evaporated from them, and, besides, washing them out, so that the frequent occurrence of an unoccupied house becoming filled with foul gases from its drains receiving no attention, is thus rendered practically impossible. This invention prevents all escape of noxious gases from drains or sinks, the danger of which is well known. Both of these inventions, though sim-

SUSPENSION DRILL MADE BY KIDD IRON WORKS.

sinks or reservoirs of a building to the drain pipe, and is so provided with valves that no foul air from the sewer can rise back into the house. In case of a fire breaking out in the lower stories, the smoke ascending the main sewer pipe will be prevented by the invention from escaping into the upper rooms through the reservoirs. A modification of the device is adapted for street sewers, to prevent the entrance of solid material to choke the drains, and the reflux of foul gases. The floodway is useful in cases of conflagrations, where water often does more damage to goods, etc., than the fire. Penetrating through flooring, it deluges everything below, ruining goods and furniture. The same occurs when water pipes burst. This floodway will rapidly draw off such water through a proper channel.

The device for ventilating and cleansing drain pipes by the same inventor involves arrangements for ventilating and for cleansing the sinks. By means of a reservoir from which distributing pipes lead to the various re-

ple, are ingenious and worth attention of insurance companies, fire departments, merchants, mechanics and property owners in general. Detailed descriptions of these patented inventions, with accompanying engravings, can be examined at 420 Montgomery street, in this city.

Suspension Drill.

The illustration on this page represents a suspension drill, of the pattern made by the Kidd iron works, Rochester, N. Y. The tool is invaluable in railroad and boiler shops. The frame is very strong and substantial. Back gears are furnished with it. The tools manufactured by these works are far the best patterns, and are very heavy. All workmanship is of the best quality and each tool is tested before leaving the works.

The rainfall for the year at Sacramento up to Wednesday, was 13.351 inches.

Salinas Mining District.

In conversation with Mr. Thomas Gilmore, superintendent of the Almaden Consolidated quicksilver mine, we recently learned some facts concerning the quicksilver mines in San Luis Obispo county. The Salinas mining district, as the district is called in which most of the mines are situated, is some fifty miles from the town of San Luis Obispo, to the northward, near the Paso Robles hot springs. The Almaden Consolidated mine has a twenty-ton furnace and some 2,000 tons of ore on the dumps. There are eight tunnels in the mine, one of which is 350 feet long. On the property is a hillock of clay which pays about one per cent. of quicksilver. The ore where they are now at work is three feet wide, but it is supposed to be only a feeder to the main body in the hill. They had up to the time the furnace was put up a one and one-half ton furnace or retort, and turned out from fifteen to twenty flasks of mercury per month. With the new furnace they have eight condensers and a chimney 400 feet up the side of the mountain to lead the fumes off. They have no true veins yet. All the feeders are rich and pitch into the mountain. The ore goes from three to four per cent., and about 500 tons of which are on the dump. The remainder will run from one to one and a half per cent. They do not do much sorting.

There are several other mines in the district. The Almaden Consolidated, San Jose, Oceanic, Santa Cruz, and the Gibson & Phillips being the chief ones in operation. The Gibson & Phillips company are putting up a furnace now, and the Oceanic has three. They are also striking ore in several different places in Monterey county. About five miles from San Luis they have recently discovered a deposit of chrome iron, and also some lead and antimony ore. They are now working a galena mine about thirty miles from the Almaden Consolidated, owned by a company in Cambria.

There are about 400 men at work on the various mines in the vicinity. Mahonysville, the central town, is becoming quite a place. There is plenty of wood and water thereabouts. The Almaden Consolidated mine is said to have a large body of ore. Some of it described as "chloride of mercury," of a peculiar white appearance, has been shown to us. This ore has heretofore been thrown away, but it has lately been found to contain about three per cent. of mercury, so it is now saved. It resembles the ore from the Reno mine, Nevada. We are doubtful, however, about its being chloride of mercury, as it would be considerably richer. Most of the stock in this company is owned by three men, and considerable money has been spent on the mine. The furnace, with engines and blowers has recently been put up, although they have been turning out quicksilver for the past year and a half with retorts.

DECEMBER WEATHER.—The Signal Service of the War Department furnishes the following report of the weather in this city in December: Highest bar., 30.353; lowest bar., 29.802; monthly range, .551; highest temperature, 65; lowest temperature, 39; monthly range, 26; prevailing direction of wind, north; greatest velocity of wind, 24 miles per hour; number of clear days, 13; number of cloudy days, 2; days on which rain fell, 10; fair days, 6; comparative temperatures—December, 1875, 51.5; December, 1873, 50.6; December, 1874, 47.8; comparative rainfall—December, 1875, 4.15 inches; December, 1872, 5.90; December, 1873, 9.72; December, 1874, .33; the daily mean barometer during the month was 30.149 inches; the daily mean thermometer, 51.5 deg., and the daily mean humidity, 81.4.

McAFFEE & SHEAR have recently furnished a large new boiler for the steamer *William Tubor*. It is 22 feet long, 15 feet in diameter and is 26 feet high over the top of the steam chambers. It has four furnaces 16 feet 6 inches wide, and weighs 50 tons. It was put in the vessel at a cost of \$18,500.

The Sinto tunnel is in 11,736 feet. The face is in good working ground, occasionally ontting stringers and feeders of quartz of an encouraging character.

CORRESPONDENCE.

The Alameda Avenue, Past and Present.

MESSENGERS, EDITORS:—Who has not seen or heard of the celebrated Alameda avenue, extending from San Jose to Santa Clara, a distance of three miles, built by the early Franciscan mission fathers about one hundred years ago? Perhaps some readers of the SCIENTIFIC PRESS, who may not have seen it, or enjoyed the pleasure of a drive under its grand old trees, would, nevertheless, like to learn something of its past history, as well as its present appearance and conditions—especially in these Centennial times, when everything that dates back for a hundred years seems to be regarded with special interest.

Alas! the old landmarks—these relics of past generations—are rapidly passing away before the march of our modern improvement. The old adobe tile-covered houses, with their venerable pear orchards and cactus plants, are passing away with the hands who built and planted them, and in a few more years they will all be numbered among the things of the past. An old Indian named Marcello died a few months ago near Alvieo, who, I am informed by the principal of the Santa Clara college, helped to plant the avenue trees in the year 1777. It is said he was a chief, the last one of his tribe. His age could not be ascertained, but it must have been several years over one hundred when he died.

These thoughts were suggested to my mind the other day, while driving along the avenue, by seeing a number of men engaged in trimming up the trees and cutting down those that had been condemned as decaying and dangerous.

Long years ago, when California gloried in her wide stock ranches, covered with wild oats and wild cattle, her low-topped spreading oaks scattered over her valleys, and everybody had leisure enough to enjoy their cooling shades, these old willow trees were permitted to grow free and easy just as they pleased, leaning and sprouting in every direction, as free and regardless of all rules of order and taste as the people who planted them were from the lumbering conventionalities of fashionable life. But these good old quiet, dreamy days are past and gone, and a great change has come. Where the patient mission fathers trudged quietly along the dusty trail from mission to mission under the shade of trees they had planted, the rumbling street cars now pass and re-pass every few minutes, and the numerous bus houses and grounds on every hand, the rattle of passing vehicles, and the hurry and stir of people in pursuit of business or pleasure, all proclaim beyond peradventure that the once lone avenue is fast becoming a busy street.

Now, of late years, a gang of men are employed every winter to go along the rows, trimming up the trees and cutting them back, trying to torture them into some kind of decent shape, as I suppose. And every year many of them are condemned to be cut for poor fire wood—"an axe is laid at the root of the tree." Thus they are rapidly passing away, giving place to others of varieties better suited to modern tastes.

As I drove along I had the curiosity to count all of the original avenue trees that remain standing. In the east-side row there are 271, and in the west-side row 330, making 601 trees—only about the one-seventh part of the original number. This calculation is based upon the way the trees stand, in the best preserved portion of the avenue. Most of the trees are the common black willow of the country, but there are a few eucalyptus and cottonwood. I had also the curiosity to measure one each of the three different kinds, selecting those of about the largest size. The willow measured ten feet in diameter, four feet from the ground, the eucalyptus eleven feet and the cottonwood twelve and a half feet; though perhaps not one half of the 601 trees would measure half as much. All of the willows are low topped, rough, bushy and crooked, and most of them look old and decaying; while the eucalyptus and cottonwood are upright and well shaped, and look healthy and vigorous. This may give an idea to what size trees of these kinds will grow in 100 years.

While in the tree measuring notion I drove over to Delmas avenue, San Jose, to interview a fine specimen of the Australian eucalyptus tree, planted only seventeen years ago. It measures six feet in circumference, four feet from the ground, and I estimated its height at 115 feet. It stands straight as an arrow—a perfect model of beauty, its dark green top towering up far above large Lombardy poplar and willow trees around it. There are thousands of these fine trees about San Jose, over-topping all trees and houses, and there may even be some larger than the one measured; but this will give your more distant readers an idea how rapidly these beautiful trees grow here. Suppose the Alameda avenue had been planted with eucalyptus trees, instead of the low-topped, short-lived willows, one hundred years ago; what kind of avenue tree would they have now made? They would rival the redwoods of the mountains in beauty and size. Or suppose some one had planted fifty acres of blue gum trees seventeen years ago on land as well adapted to their growth as that on Delmas avenue—and there is plenty just as good in the

valley—what kind of a fortune would he have to-day? Some one, perhaps, may imagine that this tree has been peculiarly favored by an isolated situation, separate from all other trees and shrubs, having a large expanse of ground to draw its nourishment from. But this is not the case. It has grown in the deep rich soil, near the Gualandoupe river, surrounded on all sides by large Lombardy poplars, willow and other trees.

Santa Clara, Cal., Dec. 21st, 1875.

Nitro-glycerine and Its Product, Dynamite or Giant Powder.

[Written for the Press by E. G. GAERTNER.]

Nitro-glycerine and dynamite have, during the last five years, almost entirely taken the place of blasting powder, and formed one of the most important factors in the career of the recent vigorous prospecting of our mines, and the enormous railway and mining tunnels lately gotten under way or completed.

For not only are the articles in question possessed of an explosive power much superior to that of powder, gun cotton, etc., but, notwithstanding all assertions, beliefs or fears to the contrary, they are by far less dangerous to handle than any other known explosive.

Manufacture.

Nitro-glycerine is made of 16 parts sulphuric acid, eight parts of nitric acid and three parts of glycerine. The acids must be of the strongest kind, the sulphuric to be of 66° Beaumé, at 62° F.; the nitric of 48° at the same temperature. The first step taken is to mix the acids in the given proportion, the produced nitro-sulphuric acid to give 54° B. at 62° F. This is poured into a number of earthen vessels, placed in a trough, each having capacity for double the amount of liquids actually used in manufacturing. The mentioned trough is filled with ice water, and the vessels in it are supplied with stirrers, which may be moved by machinery or hand. After the acid has been brought down to a temperature of 50° to 55° F., glycerine, kept in its proper proportion at each pot, may be added by pouring it, small quantities at a time, in a fine stream into the acid, keeping the same well in motion and the thermometer constantly employed. Experience teaches, that the most nitro-glycerine is gained out of the same quantities of ingredients, if the temperature is always kept at 55° F. It may be well to mention here, for the benefit of any one who should desire to try the experiment, that a drop of water carelessly allowed to fall into the pot, will cause a sudden rise of temperature, and may be the cause of so-called burning, and under unfavorable circumstances, even an explosion of the whole batch. A pot commencing to burn, that is, to fume vigorously, the only salvation is in keeping up the stirring and adding ice to the water in the trough.

After the whole proportion of glycerine has been employed in the afore-described manner, the pot is taken out of the trough, and the contents of it dumped into a barrel of water. This barrel should hang in an axis fastened to it about midway, and previous to receiving the glycerine, the water in it should be given a circular motion by moving it with a piece of board. Now the water may be poured off, all globules of nitro-glycerine swimming in it gently held back and finally the residue transferred into a tub, where it should be treated with water, until all acid reaction (on litmus paper) has disappeared. The product is pure nitro-glycerine, and can either be used as such or manufactured into

Giant Powder.

The recipes for this are so manifold, and so many of them patented, all needed being an absorbent for the nitro-glycerine, that I shall only give here one which I have used for several years, producing a giant powder strong enough for hard slate cutting: Two parts nitrate of soda; one part rosin; one part sulphur (flour); one part sawdust, are well mixed, sifted, and nitro-glycerine enough added to moisten the mixture.

Nitro-glycerine, as well as giant powder is, previous to using, put into paper cartridges coated by a mixture of rosin and tallow, and exploded in the often described manner by caps and fuse.

Exploding quicksilver caps are employed, as they most readily fulfill two conditions necessary for the exploding of nitro-glycerine and its compounds.

Heat and Percussion.

Owing to the necessity of both of these actions, nitro-glycerine is comparatively safe to handle, if it is never confined in closed vessels. However well washed the preparation may be, and however free it may appear of all acid reaction before being packed, small quantities of acid (gaseous) will be separating themselves, causing latent heat to become free and a high degree of temperature to be produced. One of the conditions of explosion being thus complied with, it needs but an accidental percussion of the vessel or box containing either of the preparations to cause an instantaneous explosion. I am well aware of what I am saying, having been convinced by my own experiments, when I maintain the following: Nitro-glycerine should under no circumstances and giant powder only when quite fresh, be received for shipment; manufacture of the articles should be done where needed, and the daily supply made daily. If this is done the article is quite safe, even safer than gunpowder, as mentioned before, and disastrous explosions will become a thing of the past.

The San Juan Country.

A correspondent of the Denver Tribune gives the following general description of the districts in the San Juan country, Colorado:

To the people of Colorado little that is new can be told about the number and richness of the silver-bearing lodes of the San Juan country. In this article I will not attempt to make any statements about the "richest mining country in the world," where we have "mountains of silver, and valleys of gold," neither will I enter into predictions of its probable future, but I will confine myself to the simple narration of facts as they exist at the present time, thus showing in what condition the country is to-day.

There are six mining districts embraced in the country: The Summit district, situated twenty-five miles southwest of Del Norte, and on the Atlantic slope; the Animas, situated one hundred and ten miles west of Del Norte and on the Pacific slope; the Eureka, just north of the Animas, and embracing the headwaters of the river of that name; the Uncompahgre, just north of the Eureka, and embracing the headwaters of the Uncompahgre river; the Lake, east of the Uncompahgre, embracing the headwaters of the Lake fork of the Gunnison river; and the La Plata, situated about sixty miles southwest of the Animas district, and embracing the La Plata river and its tributaries.

The Summit District

Is essentially a gold bearing district. In it is situated the famous Little Annie that was reported sold a few years since to Denver parties, for \$410,000. From all reports the mine is not a vein or lode, but simply a claim, taken up on a mountain, which from appearances seems to be a solid mass of mineral. Numerous claims are taken up on the mountain and they are taken up without the least regard for direction. On this mountain are situated the Golden Star and Golden Queen. Ten stamp mills have been erected on these three lodes, capable of treating about ten tons of ore daily, and are now turning out each from \$700 to \$1,000 per week. The ore averages from \$20 to \$25 per ton in gold. There are other good mines in the district, but I do not know what improvements have been made on them, and therefore can say nothing definite about them.

The La Plata District

Is also a gold bearing district. The original excitement in that section was the reputed discovery of paying placer diggings. Until the last season, placer mining was about the only kind of mining that attracted any attention there. This season a large gold lode, called the Comstock, was found, which yielded some fine specimens of gold bearing quartz, of which large assays were made. Some mining experts from California and Nevada, among whom was Mr. Phillips, examined this district during the past summer, and expressed themselves highly pleased with it. It boasts of few improvements as yet, however. There is a large ditch for the working of the placer mines, and a few lodes, with quite an amount of work done on them. The Comstock is being worked this winter.

The Lake District

Is principally a silver bearing district. Some tellurium has also been found, yielding largely in gold. No district can show a more surprising growth than this. The principal town, Lake City, has within six months grown from nothing to a place of about 400 inhabitants, among whom are many men with wives and families. The houses are newly built and chiefly frame buildings.

The mines are of exceeding richness and some of them are well developed. The Hotchkiss has about a hundred and twenty-five feet of tunneling; the Little Chieftain has some seventy-five feet; the Big Cascade, some fifty feet. Other mines have also been considerably developed, and their showing is fine. Much pay ore has been shipped from this district, and has yielded well. Smelting works have been promised for next year, and before next August they will probably be in running operation. Barlow, Sanderson & Co. run a line of stages from Canon City to Lake City. This makes the Lake district the most accessible position of the San Juan country that lies on the Pacific slope.

The Uncompahgre District.

This is a very rich district. The veins are large, and the average of the ore greater than in any other section. It is a comparatively new district, and very little development has yet been done, but what has been done has produced wonderful results. It embraces a large area, and new discoveries, each being richer than the preceding, are continually being made. On the Burrows fork of the Uncompahgre are several lodes tolerably well developed. The Dewitt and Wickers lodes each have a twenty foot drift. The Red Cloud and Ben Butler have a thirty foot drift, the drift on the Red Cloud being twenty feet wide. Among the other lodes that have little more than assessment work on them, but which show very rich mineral for their development, are the Denver, Vermillion, Updee, Marion, Burrows Nos. 1 and 2, Yankton and Mastodon.

There are two mining companies working mines in and about Burrows fork—the Dakota and San Juan and the Buffalo and San Juan mining companies. Another company has been organized, which is putting up machinery and concentrating works of forty tons daily capacity, in their principal camp, Mineral City. This town consisted of one solitary cabin last

June. It now boasts of a population of 150 persons.

On the Poughkeepsie fork of the Uncompahgre are situated some fine mines. None of them are developed to any extent, but nearly all of any note have yielded considerable ore that has brought high prices. The Saxon lode has shipped ore to Black Hawk that has brought \$1,700 per ton for first-class, \$1,400 for second-class, and \$900 for third-class. They have also sold considerable to Green & Co., of Silverton, for high figure. Two tunnels will be driven on the lode this winter.

The Tyrol, on the same vein as the Saxon, has also sold considerable ore this summer. They have a tunnel of twenty-five feet on the mine, and it is being worked at present, and will be all winter. A shaft thirteen feet deep and, in size, four by six feet, on the Alaska lode, has furnished \$18,000 worth of ore. This mine is being worked this winter. The Poughkeepsie has furnished a large amount of ore the past summer, that has brought its owners handsome figures. On Red mountain are located some fine lodes, two of them having a fifty foot tunnel each. Near Mt. Sniffles are some fine lodes, one of them carrying ruby silver, being worked this winter. Near the mouth of the Uncompahgre canon, near the new town of Ouray, some rich discoveries have been made, and a large number of men are at work there now and will be during the winter. One assay made from ore from a mine in this section was \$36,000 to the ton, showing that the ore was nearly pure silver, pure silver furnishing an assay of a little over \$37,000.

Butte County Quartz Mines—The Paul Process.

During the past summer, we frequently referred to the quartz mining carried on at Forbestown, and spoke of the place as destined to be the most important in this particular of any in the State. After all the good things we had said, we were much surprised to learn that the new ten-stamp mill had shut down and was as silent as the grave. We knew that the rock contained gold in quantities that would gladden the heart of any quartz miner. What could be the matter? We went to headquarters for our information and got it. The gold could not be saved after the rock had been crushed. We believe the same cry has gone up from hundreds of ledges all over the State. Luckily, the owners had a small stake laid away. They had heard of the Paul process and were determined to try it. It was an experiment that would cost them only about \$5,000, and if it failed they would be out that much more; but if success attended their efforts, a golden harvest was sure to be theirs. The proper machinery was bought and soon placed in position. Does it save the gold? Look at the jolly countenance of any of the owners in the mine and the answer will be plainly seen. A couple of them visited us one day last week, and we took occasion to make all the inquiries that we dared make, lest they should think we were too much interested in their business. The rock they are now crushing pays from ten to forty dollars to the ton, and they save almost all of the gold. They run night and day, but with their small mill crush only ten tons during the twenty-four hours. They might crush more, but the Paul arrangement will not dispose of a greater amount. The grinding and setting process is only ten tons per day; but, though small, it is done in a most satisfactory manner. The mine that is worked during the winter season is only some 200 feet from the mill, and the rock is easily run into it upon a car. There is every prospect now of complete success, and failure can only result from a want of rock.—Oroville Mercury.

The Glencoe Consolidated Mine.

The Calaveras Chronicle says: We understand that the company lately incorporated, under the title of the Glencoe Consolidated, for the purpose of conducting mining operations in Glencoe district in this county, are preparing for the commencement of developments upon a very extensive scale. The company's location is one of the most promising mining properties to be found anywhere. The ledge is easily traceable, by surface croppings, for a distance of two miles, and evidences that the lode is a true and permanent one are found at every step. The formation is also of a character that almost invariably gives stability to the veins it carries, and the lode is accompanied, its entire length, by that soft blue gangue that practical miners accept as the most favorable indication possible. The ledge is a mammoth one, averaging six feet in thickness, carrying an extraordinary rich pay streak averaging fully three feet in width. But more tangible evidence of the richness of the ledge has been had than an accumulation of all the favorable indications in the world could give. A shaft has been sunk upon it to a depth of eighty feet, the ore extracted yielding an average of \$40 per ton by ordinary milling process. Everything considered, we do not believe a more promising location for successful mining operations than that chosen by the Glencoe Consolidated company can be found anywhere. The facilities for the erection and working of machinery are excellent, and in fact no opportunity for rapid development is lacking. As soon as the condition of the roads and estate of the weather will permit, operations will be vigorously pushed upon a much more extensive scale than has been customary in the upper country.

MECHANICAL PROGRESS

Stencil Plates by Electro-Magnetism.

One of the most ingenious and novel applications made of electro-magnetism, is that invented by Mr. Edison, and exhibited at the fair of the American Institute in New York to perforate stencil plates by means of an electro-magnetic writing pen, which has in its blunt end a sharp point which is continually projected and retracted with a velocity of more than 1,000 times a minute, so that in writing with this pen on paper the lines written consist of a series of holes very close together, and the words written or figures drawn may be seen when holding the paper to the light. The sheet thus written upon forms a kind of stencil plate, and being placed on paper, an impression may be taken from it by simply passing a proper ink over it by means of a printer's roller, when the ink will pass through the holes and make their marks on the paper under it. In this way 1,000 or more impressions may be made from a single stencil-plate thus written by the electro-magnetic pen.

The construction of this pen is the main feature of the invention. It carries in its top a small electro-magnet with a revolving bar, making some 1,000 or more revolutions per minute; the electro-magnet is connected by means of flexible copper wires to two small cups of a carbon chromic acid battery, while a current breaker on the axis of the revolving bar, interrupts the current twice at every revolution, in the same way as all such machines are constructed. This axis also carries an eccentric, which gives an upward and downward motion to a bar passing through the body of the pen and projecting below with the small point mentioned, while this point makes the perforations by the power of the electro-magnet in the top of the pen. We have no doubt but that this small machine will find many other applications besides that of writing circulars, for which at present it seems to be solely intended.

TWO NEW STREET ENGINES.—A new traction engine for street usage has recently been tested in Brussels, Belgium, with satisfactory results. Externally it resembles an ordinary street car, with the exception of the chimney which projects through the roof. The body is placed quite low, and the wheels, which run on rails, are concealed to within a short distance from the ground. The boiler is tubular and inextensible, and is heated by coke. The engine is one of the Brotherhood three-cylinder pattern. The exhaust is condensed in a tubular condenser, and the boiler is fed by a separate steam pump. The machine traveled without smoke or escape of steam, made no more noise than an ordinary horse omnibus, and turned sharp curves very easily. Another engine is introduced in Paris; but instead of running on a tramway like the above, it is a kind of omnibus or steam carriage. It accommodates twelve passengers and weighs about five tons. A vertical engine supplies the motive power and occupies a space in the rear of but thirty-nine inches high by thirty-one inches broad. A Giffard injector forces in the feed water, which is taken from the gutters or any other convenient source. The machine will travel at the rate of nine miles per hour. About thirteen-horse power is utilized, requiring 600 quarts of water, and 110 pounds of coal per hour.

COMPOUNDING STEAM ENGINES.—The controversy as to the possible economy of compound engines has been long ago settled, and the advantages of the additional cylinder and piston, to be operated by the steam exhausted from the first, have been proved beyond any doubt. But the economy is not derived, as some seem to think, from using steam twice, for whether the steam passes through one cylinder or forty, the difference between the pressure of the steam at its entrance to the first cylinder and its final exhaust into the atmosphere is the sole power which the engine can exert. The low pressure, larger cylinder added to an engine, while it discharges its steam at lower tension, creates a certain amount of back pressure in the first or smaller cylinder; and there is, therefore, no positive gain of power in a compound engine. But the larger cylinder enables that little understood and most important part of steam, its elasticity, to be much utilized; so that it may be said that the additional cylinder is equivalent in result to a very effective cut-off.

BREAKING WEIGHTS.—A correspondent of the *Scientific American* writes as follows: Some time since I ordered some short timber to be placed on some joists in my shop, and left. When I returned I found it all placed on two joists, and I took one-third off. Twenty-four hours afterward the joist broke. Why did it not break when all the timber was on? To this query that journal responds: Time is an element to be taken into consideration in overcoming the strength of the fibers of timber. Two-thirds of the load in this case was sufficient to break the joist in twenty-four hours after one-third had been removed; but a much shorter time would have sufficed to break it with the whole load upon it.

WHILE steel is made harder and stronger, in proportion to a certain amount of contained carbon, cast iron, when it is very rich in carbon, is soft like plumbago, will break by its own weight, and may be cut with a knife.

Novel Water Motors in Mines.

At the Sulzbach, Altenwald colliery, near Saarbrücken, Prussia, machinery has been established for the transmission of power from a steam engine at the surface, by a column of water circulating under pressure, the circumstances of the case not admitting of the establishment of a direct acting steam pump underground. The mine is sunk 306 yards below the surface. The piston rod of the high pressure engine above is connected with the pressure plungers, each of which plungers is connected with the underground engine by a tube filled with water. The last mentioned engine consists of four pressure pumps arranged in pairs, and between each pair is placed the working plunger of one of the mine pumps. When the engine on the surface acts, the power is transmitted by one pressure plunger through one water tube to a pair of pressure pumps underground, and thence to one working plunger, which either aspirates or forces air, according to its position. The opposite pair of pumps and connections work conversely. The water is forced into an air vessel, and thence through the rising main 803 yards in height, in one lift to the surface. On the change of stroke, the water in the cylinder of the pressure pump rises in the second water tube and follows the retiring pressure plunger at the surface, the power supplied by the descent of the water in one column being sufficient, with the exception of a slight allowance for friction, to effect its return in the other. If the catalyst pauses of the engine at the surface are not too long, the discharge is practically continuous. The *Engineering and Mining Journal*, from whose translation of the German description the above is condensed, adds that at the Pboeniz mine, in Cornwall, England, an arrangement of similar description, consisting of a plunger attached to the main pumping engine, connected by a length of tube with water pressure engine in another shaft, has been at work for the last ten years.

A Machine for Darning Stockings.

The *Scientific American* thus describes the latest Yankee notion: "Imagine, ye mothers of large families, who ruefully contemplate dilapidated socks by the dozen, after the week's washing, with visions of strained eyes and tired backs floating across your minds; imagine a little apparatus infinitely more simple than the sewing machine, which repairs the largest darn in much less time than we can describe the operation, and far more neatly than you can do it with all your years of practice. This is what it is. Two small plates, one stationary and the other movable, are placed one above the other. The faces are corrugated, and between them the 'holy' portion of the stocking is laid. Twelve long eye pointed needles are arranged side by side in a frame, which last is carried forward so that the needles penetrate opposite edges of the hole, passing in the corrugations between the plates. Hinged just in front of the plate is an upright bar, and on this is a crosspiece carrying twelve knobs. The yarn is secured to an end knob, and then, with a bit of flat wire, pushed through the needle eyes. Then the loop between each needle is caught by the hand and hooked over the opposite knob, so that each needle carries really two threads. Now the needles are carried back to their first position, and, in so doing, draw the threads, which slip off the knobs through the edges of the fabric. A little push forward again brings the sharp rear edges of the needle eye against the threads, cutting all at once. This is repeated until the darn is finished, and beautifully finished it is. The inventor is Mr. O. S. Hosmer of Boston, and we predict for him the blessings of the entire feminine community. The cost of the machine is but ten dollars."

AN IMPROVED BARREL.—Mr. L. E. Sunderland, of Williamsburg, Va., has devised a new style of barrel, the object of which is to provide a barrel for the shipment of produce, which shall be capable of transformation after the said produce is delivered, so as to occupy a comparatively small space, and be returned to the sender at the rates of solid freight and at a comparatively trifling cost. It consists in a series of staves, connected by hoops which have peculiar fastenings, which adapt the staves to be disposed flat for return transportation, or rolled up and fastened to form a barrel. The sides of the barrel are straight, and the heads are held in place by lugs alternating, when the barrel is set up upon opposite sides of the head. The heads are thus of less diameter than the inside of the barrel, so that the barrel, when returned, may be packed full of heads, and the rest of the barrel sides packed flatly together.

THE DUNDERBERG, or Stevens battery, which this government allowed to be sold to the French government, is now considered one of the most formidable war vessels in the French navy, where she is known as the *Rochambeau*. She is an immense iron-plated ram, displacing 7,000 tons of water, and has a larger deck surface than any war vessel ever constructed.

SOFTENING AND TIGHTENING WOOD.—If blocks of wood intended to be used for cutting veneers are first boiled or steamed in a solution of ammonia and borax, they will not only become soft and easy to cut, but the veneers formed from them will retain their flexibility for an indefinite length of time.

SCIENTIFIC PROGRESS

How Flames Become Luminous.

Professor W. Stein, in a recent number of the *English Mechanic*, thus intelligently discusses on the Luminosity of Flames.

The correctness of the old and well-founded conception that the light of flame is caused by incandescent carbon molecules, has been disputed by Dr. Frankland, who contends and tries to prove that it is derived from hydrocarbon vapors.

As proof of his ideas he mentions that the soot deposited on a cool surface, when introduced into a flame, does not consist of pure carbon, but that it contains also hydrogen; that, in fact, it seems nothing else than a collection of the densest light-giving hydrocarbons, whose vapors condense on the cold surface.

Against this we may mention they not only do the heavy hydrocarbons, but even marsh-gas, split up at high temperatures on exclusion of atmospheric air; and as the hydrocarbons, whose vapors are supposed to cause the luminosity of the flame, are precisely under such conditions before they come into contact with the air, it cannot be doubted that they suffer decomposition into carbon and hydrogen in the luminous portion of the flame. It is of little importance whether the eliminated carbon is chemically pure, or whether it contains still a hydrogen compound; the important question is this—Is the soot held by the flame in the shape of vapor or in the solid form? If the soot was nothing but a conglomeration of the densest light-giving hydrocarbons, whose vapors condense on a cool body, then, when sufficiently heated by exclusion of air, it ought to reassume vapor form. This is, however, not the case, as every one will find who tries the experiment.

Its chemical composition is just as little favorable to Frankland's view. It ought, presumably, to vary according to the lighting material from which it was derived—nay, even according to the place of the flame wherefrom it was deposited. It is well known that the temperature of the flame varies in various places, and Magnus experiments have proved that form heavy hydrocarbons at a less high temperature a hydrogenous tarry product besides hydrocarbon is also eliminated.

"How could the light of a flame be as transparent as in reality it is, if it was filled with solid carbon particles?" asks Dr. Frankland.

In reply to this, it must be admitted that one is able to read the writing held behind the flame of a bat's-wing burner. It is, however, easily observable that the flame is more transparent in the lower non-luminous portion. The reading also becomes more difficult through a flame of greater thickness, and impossible through the flame of a candle or petroleum burner. If, as is proved hereby, the transparency of a flame is only very limited, it may also be remembered that one can also read the same writing through media which are known to be filled with solid particles. The fact that solid bodies are by preference apt to become light-radiating is not at all changed by this, and thus far it is demonstrated only that there can be but one solid body to which the luminosity of light can be attributed. If we consider, therefore, all the facts, we can draw only one conclusion, namely, that the light of illuminating flame comes from incandescent carbon molecules, and that the old view is still to be retained.

NEW CLASSIFICATION OF BODIES.—Mr. Mendeleeff, a Russian chemist, classifies all known bodies, elementary and compound, by an arrangement of vertical and horizontal lines, according to the likeness or dissimilarity of these bodies and the numerical value of their characteristic elements. He thus makes a double table in which all known bodies are arranged, so that it is possible to pass from one to the other by the multiplication of one factor by another. Remarkable that a large number of gaps occur in this table, he thinks it probable that they correspond to bodies unknown at present, the existence of which will one day be discovered. According to the relative position of these gaps he is able to show beforehand their properties and characteristic numbers (equivalent weight, density, etc.) If, for example, this table had been made before the discovery of bromine, the place of the latter could have been anticipated between chlorine and iodine, and its properties pre-indicated. The newly discovered metal, gallium, occupies a place which was blank in Mendeleeff's table, corresponding to a body which its author would have named by hypothesis hexaluminum, with a density 0.9.

NEW MODE OF ILLUMINATION FOR LIGHT-HOUSES.—Prof. Batestrieri, of Naples, proposes for this purpose an apparatus composed of several disks of polished silver or copper, so arranged as to transmit successively the light received, so that all the rays falling upon the disks are concentrated into one powerful beam. The invention resembles the system of Fresnel, but the latter utilizes only about one-third the light received, while M. Batestrieri's device, it is said, utilizes the greater portion. With an oil lamp having a burner 2.7 inches in diameter, at a test of the above described apparatus, a beam of light was transmitted which enabled a newspaper printed in ordinary type to be read at the distance of 0.6 of a mile.

A New Method of Finishing Photographs.

In the first place enamel your print, as enameling, though not absolutely a *sine qua non*, is a decided advantage. We will suppose this has been effected, the subject having been printed in an oval. Now let a mask be constructed, of eight-sheet cardboard, of sufficient size to entirely cover the enameled and mounted picture, with margin to spare; glue a piece of sand-paper on one surface, rough side out, and when dry cut out an aperture of the exact dimensions of the picture to be finished, taking care the edge is accurate and smooth; adjust this paper die, so to speak, on the face of the enameled picture, and apply pressure. Passing them through an ordinary rolling press answers the purpose well. The result is that the parts in contact with the sand-paper surface are roughened or rendered matt, offering a pleasing contrast to the polished surface of the picture, and in this consists the novelty.

Paper lace and various textile and other fabrics can be substituted for sand-paper, or a metal plate could be engraved to produce any pattern. Many substances will suggest themselves to the experimentalist, and variety of ornamentation can be easily devised by altering the shape of the mask. For my own part I prefer sand-paper to most other substances. Any degree of fineness of surface may be got by this means, and by slightly shifting the position of the mask and putting through the press after each alteration.

I think that ornamentation, when produced by merely altering the texture of the surface, is of a much more refined character than when gold or color is applied for the same purpose. The plan here described has been found thoroughly workable with little trouble and less expense, as one sand-paper mask will impress a great number of surfaces, and its renewal is most easily managed. All I can say to photographers, more than this, is to advise them to try it.—*British Journal of Photography*.

Lighting Coal Mines From Without.

The frequent and terrible disasters which so often occur in coal mines from the use of lamps—even the best devised so-called "safety lamps"—render any possible device for their exclusion a matter of the utmost interest to this great and important industry. To this end the *Scientific American* suggests that this could be accomplished very easily, it believes, by the generation of the light without the mine (or else at the foot of a ventilating shaft), and its conveyance through tubes to the points requiring illumination. Beams of concentrated light could be sent to any distance through pipes having reflectors suitably placed at bends and angles, or without reflectors, provide the interior of the pipes were smooth and bright. The cost of such lighting would probably be less than the cost of lamps, and the degree of illumination might easily be such as to flood the mine with the brilliancy of daylight.

Another substitute for treacherous safety lamps might be found in electricity, the lanterns being closed so as to make it impossible for explosions to occur. If the insulation of the conducting wires should prove a serious obstacle, it is quite possible that Mr. Edison's "etheric force" would do the work as well without insulation.

ELECTRICITY IN THE MACHINE SHOP.—A correspondent of the *Scientific American* writes: "The electricity produced on an engine, by the friction of a cross belt 100 feet long and three wide, is considerable. By holding one hand up within a foot or so of the belt, and with the other touching a gas jet with a copper wire, we easily light the gas, even if the wire is held an inch from the jet. In some conditions of the atmosphere, it is very painful to walk bareheaded under the belt, although it is some twelve feet or more from the floor. A number of persons have received great relief from rheumatic and neuralgic pains and nervous headache by standing under this belt on zinc or glass plates. The question is this: Can I, with copper or other wire, collect a part of the electricity from the belt and convey it a quarter of a mile so as to utilize it?" Yes, answers our cotemporary, but it will cost more to do so than to generate electricity where it is wanted.

STONEHENGE.—Quite recently a party of civil engineers proceeded to this famous locality in England and were engaged for four or five days in taking most elaborate measurements of the structure, as well as making astronomical calculations. The results of their exhaustive survey have been very striking, astonishing, it is said, none more than the *savants* themselves, and leave not the least doubt about the solar references of the structure; and, further, that it was undoubtedly erected as a temple of the sun.

SOUND MADE VISIBLE.—A sound writer, called an opidoscope, is a new invention. On the end of a two inch tube is pasted a piece of thin rubber or tissue paper. In the center of this is fastened a piece of looking glass, one-eighth of an inch square. Hold this end in the sun and the other end in the mouth, and sing or speak in it. The ray of light reflected from the mirror falling on a white surface describes curves and patterns differing for every pitch and intensity, while the same conditions give uniform results.

Sales at S. F. Stock Exchange.

Table with 2 columns: Date (FRIDAY, A.M., DEC. 31., MONDAY, A.M., JAN. 3., WEDNESDAY, A.M., JAN. 5., THURSDAY, A.M., DEC. 30., THURSDAY, A.M., JAN. 6.) and Stock Prices (listing various stocks like Alpha, Beta, Gamma, etc. with their respective prices).

Table with 2 columns: Stock Name and Price. Lists various mining stocks such as 315 Mexican, 895 Ophir, 1310 Savage, etc., along with their current market prices.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.

Table with 10 columns: Company, Location, No. Amt. Levied, Delinq't, Sale, Secretary, Place of Business. Lists mining companies and their shareholders.

OTHER COMPANIES—NOT ON THE LISTS OF THE BOARDS.

Table with 10 columns: Company, Location, No. Amt. Levied, Delinq't, Sale, Secretary, Place of Business. Lists additional mining companies and their shareholders.

MEETINGS TO BE HELD.

Table with 5 columns: Name of Co., Location, Secretary, Office in S. F., Meeting Date. Lists upcoming meetings for various mining companies.

LATEST DIVIDENDS (within three months)—MINING INCORPORATIONS.

Table with 5 columns: Name of Co., Location, Secretary, Office in S. F., Amount Payable. Lists recent dividends for mining companies.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR. BRIGHT PROSPECTS.—Amador Ledger, Jan. 1: The outlook at the present time for Amador county is exceedingly encouraging. Since the commencement of the rainy season there has been a wonderful revival of mining industry.

considerable item in the way of hauling. LAND SLIDE.—A large land slide occurred on Friday of last week on the Amador canal company's gravel claim, just beyond Jackson Gate. A great portion of the hill, partly undermined by the hydraulic operations and thoroughly saturated by the heavy rains, slid bodily a distance of about 100 ft, entirely covering the "Big Giant" with debris.

nance stack, suggested by comparison of the structures of this character which are thought to be of material advantage. The location of this furnace is at the base of the mountain, at the head of the main street, and is very convenient for the receipt of ores from their mines, as it also is for the delivery to the works of coal and other supplies. The buildings are all included under one roof, the extreme height of which from the ground is 25 ft. The different rooms are of the following dimensions, viz: Engine room 20x27 ft; furnace room 32x35 ft; ore room 16x22 ft, with separate apartment for rock breaker 8x12 ft. In the engine room is located the driving power, consisting of a 25-horse power engine manufactured at the Golden Gate iron works and of neat and substantial pattern. In this room is also located one of Baker's patent blowers, No. 4 in size, and which will easily furnish blast sufficient for a furnace of this capacity. The furnace room contains the stack only and is ample and roomy to accommodate the workmen. The stack is built on a substantial stone foundation, upon which rest the columns that support the diaphragm, all of which are strong and massive and amply sufficient to support the weight which they have to bear. Above the stone foundation upon a tier of fire brick rests the water jacket, which differs from that used in the Deane furnace, and which is in general form of the same pattern as have lately been introduced in the smelting works of the Richmond company in Eureka, Nevada.

NEW COSO.—This company is still engaged in prosecuting work upon their mines with utmost energy and activity, having as large a number of men employed as can be worked to advantage. They are sinking and drifting in so many places that it is really confusing and bewildering to a mining novice to explain the different points being explored.

NEVADA.

OSCEOLA.—*Foothill Tidings*, Jan. 1: This old mine, situated over on Squirrel creek, now under the management of Mr. John T. Rodda, is one of those sulphuretted lodes which will be brought into prominence by the successful practical working of the Fryer process. We learn that Mr. Rodda is having a lot of his rock tried by the Fryer method and feels sanguine of making it a paying mine.

EMPIRE.—Last week this mine produced 213 tons of ore and the mill reduced 240 tons. The ore in the south drift on the 10th level shows a slight improvement.

Not much in the way of local items transpiring these days. Everybody waiting to see what the completion of the railroad and the practical working of the Fryer reduction process will bring.

EUREKA.—The clean-up of this mine for five days of last week gave 175 ounces of amalgam. The ground in No. 3 shaft is more favorable and sinking and timbering progresses at the rate of a foot per day.

SAN DIEGO.

JULIAN AND BANNER MINES.—*San Diego World*, Dec. 14: It is so seldom that we have any Julian news in the San Diego papers, that the outside world might think we had necessarily dried up and gone quite out of existence, when in fact the contrary is the case. We hold our own in the matter of population, and so far as I am personally concerned, also hold my own (inasmuch as I came here broke). I believe also, that I have a great many neighbors who are correspondingly happy.

Laying all jokes aside, it may be truly said that our farming population have not only increased in numbers, but are generally in a more thrifty condition, having, in a great many instances, built comfortable houses and barns. Their stock of cattle, hogs, sheep, horses, etc., have increased in both numbers and value; they have invariably had good harvests and remunerative prices for their products; therefore I must say, in so far as our farming community is concerned, we are prosperous.

However the mining system has not advanced as much in the past year as we had hoped for.

There is a great deal of prospecting done at the present time in this mining region.

The wonderful Tom Scott mine made an immense clean up a few days since, the crushing consisting of three tons of rock. It is reported in town that an immense explosion had taken place in this mine, consisting of a spontaneous combustion of about fifteen pounds of giant powder at the bottom of the shaft, near which two men were working, the result of which has not been truthfully made known to your correspondent at this time.

The Pride of the West had a crushing a few days since of eighteen tons of ore, the result of which was \$46 per ton.

There was a lot of rock crushed from the Big Blue that paid about \$50 per ton.

In the Canon, the Hidden Treasure had a clean up of about \$8 per ton.

The Ella mine is being pushed ahead with energy, and the outlook is very promising.

The Madden mine has been leased by George Cooper and others, and they have struck a fine body of ore.

Work on the Mammoth tunnel has been suspended for a few weeks past, but work will be resumed on the first of the month with renewed energy. This will do more toward developing the country than all the balance combined, tapping, as it will at great depth, the principal ore chimney in this gold system.

There is a considerable prospecting being done here at present for mica, in large quantities, with what result deponent saith not.

Nevada.

WASHOE DISTRICT.

LADY BAYAN.—*Gold Hill News*, Dec. 30: The pump station is completed at the 500-ft level, and sinking the main shaft was energetically resumed last Tuesday morning. The main south drift on the 300-ft level is being steadily advanced, the face in ore of good character. The upraise from the 380-ft level is also in ore. The main south drift on the 380-ft level is steadily advancing, the face in quartz of a very encouraging character. The main southwest drift on the 170-ft level is looking much more promising for an ore development than it has for some time past.

LEVIATHAN.—All work at the 420-ft level is discontinued at present, in order to concentrate all forces upon the sinking of the main shaft deeper. The shaft is to-day down to the depth of 450 ft, and at 500 a level is to be opened to prospect and work the mine at that depth. There is but little doubt that the fine vein of ore already developed at the 420-ft level extends deeper, and will be intersected by the proposed new level.

ORIGINAL GOLD HILL.—Daily yield, 20 tons of ore from the south ore body. The breasts and stopes are looking finely with plenty of ore in sight to last for months. Work in the north drift is suspended at present on account of foul air. The Hope mill is running steadily on ore from this mine, crushing twenty tons a day. The pulp assays average from \$30 to \$40 to the ton, and the first clean-up of the mill will be made to-morrow.

BULLION.—Sinking the main incline is going forward steadily, the bottom in good working ground. Burleigh drills are being placed in the face of the north drift on the 1700-ft level. These drills will add greatly to the speed and comfort in working that portion of the mine.

CHOLLAR-POTOSI.—Daily yield, 60 tons of ore, the assay value of which is \$28 to \$30 per ton. The new combination shaft is now down 500 feet.

GLOBE CONSOLIDATED.—The face of the main south drift on the 350-ft level is showing some very good ore, although it is in spots, it appears to be gradually becoming more concentrated and of a better quality. The north drift on the same level is also looking quite encouraging.

NORTH CARRON.—The ledge is developing finely on the tunnel level, and promises a much better ore formation than was at first expected.

CONSOLIDATED VIRGINIA.—Daily yield, 500 tons of ore. Owing to the mill being unable to crush it, and the teamsters being unable to haul it to the mills, the supply of ore has been temporarily reduced to the above amount. The ore-breasts and stopes throughout the mine continue their regular yield of rich ores, and show no signs of diminution whatever. The mills are running up to their full crushing capacity, and the regular dividend may confidently be looked for, although it may not be quite so large as heretofore, owing to the late start in the month of the mills.

OPHIS.—The new pumping and hoisting engines are working splendidly. The flow of water is now readily taken up by the pumps at the 700-ft level. In the shaft it is reduced to 30 feet below the 1500-ft level, where it is allowed to remain pending the reparation of the drifts and winzes on that level; these drifts are badly caved, as are also the north and south winzes, extending downward from the 1500 to the 1600-ft level. Both these winzes are closed, so that it is impossible to yet ascertain the amount of actual damage done. The main drift on the 1600-ft level is also badly caved, and the east shaft is full of water, which will have to be taken out with the air engines run by the compressors as soon as work can be comfortably resumed at that point. The erection of the incline hoisting machinery is making good progress.

JULIA CONSOLIDATED.—The 1600-ft station is nearly completed, ready to start a drift to cut and prospect the ore at that point. The main drift on the 1400-ft level is steadily advancing, the face almost entirely in quartz and low grade ore. The character of the quartz encountered at this point is very encouraging. It is seven feet in thickness, and bids fair to lead to more and better ore deposits.

KOSATH.—Sinking the south winze below the 200-ft level is making good progress, the bottom still in quartz and ore of a good quality. Everything in and about the mine is in good working condition.

CALIFORNIA.—Sinking the C. & C. shaft is making excellent progress, the rock in the bottom blasting out finely, and the work being pushed with all possible energy. The erection of the California mill is going forward as fast as men can perform the work and do it well. It will be ready to run in about twenty days. But little work is being done in the mine, owing to the want of dump room.

OVEMAN.—Cleaning out and repairing the main shaft below the 1100-ft level, preparatory to resuming sinking, is making good progress.

ROCK ISLAND.—The quartz and ore in the south drift, on the 650-ft level, is showing more of an improvement as the drift gradually progresses to the southward.

EUROPA.—Yesterday morning the face of the main west drift on the 320-ft level penetrated the east clay porphyry, and passed into fine white quartz of a very encouraging nature. The main ore vein cannot certainly be very far away.

SERRA NEVADA.—Sinking the main shaft is making rapid headway. The tank station at the 1200-ft level is completed, and the main south-

west drift, on the 1000-ft level, is steadily advancing, the face in soft ledge material.

NORTH CONSOLIDATED VIRGINIA.—The rock in the bottom blasts out well, and although the flow of water is steady, yet it is not strong enough to at all interfere with the headway. The machinery works well.

DATTON.—The 500-ft station is completed and a drift started to cut the ledge at that point. Sinking the main shaft has been resumed and is making excellent headway.

BUCKEYE.—The ledge is still showing very promising in the bottom of the winze south of the main shaft on the 500-ft level.

CAWSON POINT.—Daily yield, 425 tons of ore, keeping the mills all steadily running. The main south drift, on the 1600-ft level, is steadily advancing to connect with the south winze from the 1500-ft level. This winze is also making good progress, the bottom still in ore.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. The ore breasts show a slight improvement over last week. The north drift on the 2000-ft level is showing a decided improvement during the past few days, and the appearances are very favorable for ore developments in that portion of the mine.

SOUTH COMSTOCK.—The material in the face of the cross-cut has become considerably softer and of a more favorable character during the past week, showing occasional streaks of quartz giving low assays.

BALTIMORE AND AMERICAN FLAT.—The new station at the 1050-ft level is completed and a drift started to open and prospect the ore vein at that point.

AMAZON AND GLASGOW.—The main shaft is down 66 feet below the second station level, with occasional stringers and feeders of lively quartz and ore coming in, although the pitch of the feeders appears to be much nearer perpendicular than was shown by the dip of the ledge on the levels above.

SULLIVAN.—A drift has been started south on the ore vein at the junction of the tunnel and shaft. The ore in the face of the drift is becoming more concentrated and is of a better quality than any heretofore encountered.

LEO.—The face of the south drift from the bottom of the winze below the tunnel level is still in good ore. The cross-cut from this drift is also in ore of a better quality than has heretofore been encountered.

JUSTICE.—Daily yield, 30 tons of ore. This ore is being taken from the 400 and 600-ft levels and is of a good milling quality.

NEW YORK CONSOLIDATED.—Prospecting the 800-ft level is still vigorously prosecuted, with good prospects of ore developments ahead.

NEVADA.—The main north drift following the course of the ledge is steadily advancing, without change. The winze being sunk below the level of the east cross-cut from the south drift is developing some very favorable spots of ore.

SUCCESS.—The water is again nearly extracted from the shaft, ready to resume sinking. The north drift and west cross-cut on the 550-ft level are each steadily advancing, the face of both in much softer and more favorable ground.

PROSPECT.—Sinking the main shaft is going energetically ahead, the bottom in good working ground.

Arizona.

LOCAL AFFAIRS.—*Arizona Miner*, Dec. 25: Thomas Gardner came in from the Trench mine on Thursday. Twelve men are now at work and more will be as soon as he returns with necessary tools. Ore is being taken out of two tunnels—one run from the surface, and another from the bottom of a shaft, about one hundred feet down. We particularly inquired of him about the quantity of ore, and he promptly replied that it was plenty and rich. Smelting will soon commence.

Workmen have been put on the San Xavier, and within a few months that mine will be made productive.

Mr. E. N. Fish is now on a trip with Dr. Bronson and Maj. Blakeney to the Patagonia, and Governor Safford will meet them at the mine.

Joseph Collingwood writes us that Nimau & Nash's mill at Stoneman, between Florence and Pinal, is about ready to start up.

Dr. C. Lord has sent Mr. Libby, a machinist, to Apache pass to examine and report upon the condition of a 10-stamp gold mill that has been lying idle there for some years, with the view of turning it into some practical account in this neighborhood.

D. C. Thompson has been in this week, from the Ostrich mill and mines about there, and reports as favorably as we think a man ought. He says the practice of exaggeration is bad, and that he will not encourage it, but is entirely contented with the show of ore in that section both as regards quality and amount.

Colorado.

BURNING OF THE STEWART REDUCTION WORKS.—*Colorado Miner*, Dec. 25: About two o'clock last Sunday morning, the alarm of fire was heard in the streets, and it was soon known that the large silver mill of the Stewart silver reduction company was in flames! Crowds hurried to the spot; the Georgetown fire company had their apparatus early on the ground; everybody worked with a will; but the consuming fire had secured a headway that no power could control, and in a short time the grand establishment, with its complicated and expensive machinery, was in ruins. Four years ago, the same wild alarm rung out on the stillness of a Sabbath morning, and the flames swept away the predecessor of this mill; then it was a heavier blow than now to our mining interests, but the feeling of sympathy with the owners of

the works is as great now as then. In rebuilding the works, Mr. Stewart had taken every precaution against disaster from fire, and the mill might have been termed safe in this respect, and it was only some utterly unforeseen accident, such as that which happened, that could have wrought the ruin that has occurred. The mill had been closed for Sunday, according to the usual custom; and there were but five men about the place, cleaning up on different floors, when the headlight in the battery room exploded, scattering the blazing oil upon the dry pine timbers; three of the men, as soon as they could reach the spot, commenced fighting the fire with ore soks, while the other two rushed for water and the hose. Before water could be got on, however, the flames had spread in the dry pine beyond the control of those who were fighting them, and as the fire leaped along under the roof, it was soon a foregone conclusion that the building was doomed. We knew nothing of the fire until the next morning, but many who were present have spoken to us in the highest praise of the exertions of the firemen and other citizens to save the building and adjoining property, which undoubtedly resulted in preventing the destruction of the office and melting and assay department, and the new building in which there is about \$10,000 worth of machinery, and bullion-producing by the leaching process is still going on. The loss involved by this fire is in the neighborhood of \$100,000, upon which there is an insurance of \$60,000.

The closing of the Miners' national bank was in accordance with orders from stockholders in the East who were in control. The cashier, Mr. Phelps, wishes us to return thanks on behalf of the bank to the business men of Georgetown, who so generously came forward, not only with the expression of sympathy, but material aid.

Utah.

PARK CITY MINES.—*Salt Lake Tribune*, Jan. 1: The latest news of importance is that the Ontario company have rented the Marsac mill, and intend running that and the McHenry mill (twenty stamps each), so that the yield of bullion from that mine will be doubled, commencing with the New Year. The yield of ore for the next year will be quadrupled. Several new locations were opened during the past summer—supposed to be on the Ontario lode and some of them are promising veins. Many other locations were opened in various parts of the district, which promise an abundance of ore. The greater portion of the ores of the surrounding hills are smelting, and a smelter is of the very first importance to the miners, and would pay well. There is plenty of wood and coal in the immediate vicinity, and during material also.

The gangue of most of the mines on the ridges extending towards the Cottonwoods is an ochre, containing a large percentage of iron, yellow and red oxides, while much of the best ore is a carbonate of lead mixed with oxide of iron, with all the forms of limestone, so that it may be said the lodes themselves contain their own fluxing material. In five years more this district will number its good paying mines by the dozen.

The Ontario is situated near the eastern terminus, and in a depression of the long mountain ridge that once extended from the Oquirrh to the Uintah chain of mountains, embracing Little and Big Cottonwood and American forks. This ledge was mineralized (so far as known and explored) about ten miles in width by thirty or forty in length.

It is believed by those who have carefully examined the subject, that American fork, Little and Big Cottonwood and the ridge extending through Parley's peak, were once on an unbroken chain of the Wasatch, and that the canons that now extend north, south, east and west from the summits, were torn out by the receding waters of what was once a vast inland sea.

The Knickerbocker mine has had a very strong flow of water to contend with for some time past, in fact one of the largest pockets yet found on the line of the Comstock. However, the pumping machinery is getting the better of it, and there are undoubted signs of a rapid draining of the whole so as to permit the resumption of work on the 600 and 700-ft levels.

The latest advices from Wrangel state that the snow lay three feet on a level and the cold was intense. The Stickeen river was frozen. A party of men were one month reaching Wrangel from Telegraph creek. The trip occupies about one and a half days in the summer season. The animals are all doing well, and a large immigration is anticipated in the spring.

The shaft repairs in the Hale & Norcross mine are completed down to the head of the main incline, and work has been resumed at all points on the 2200-ft level, the same as before the suspension for repairs. The lower drifts and levels were all found in the best working condition possible, and everything is again running all right.

The water has not yet been drained from the Gould & Corry shaft, on the 1700-ft level; consequently no work can be done in that portion of the Best & Belcher mine as yet.

The Cheyenne Leader estimates that 10,000 people have gone to the Black Hills mining region during the last three months. They have come from all directions—from the South, Utah, California, Nevada, Idaho and Montana.

Prof. Rogers' Report on the Bonanza Mines.

In the annual report of the Director of the Mint, is incorporated the following report of Prof. R. E. Rogers on the Consolidated Virginia and California mines:

Hon. H. R. Linderman, Director of the Mint—Sir: In compliance with your request of November 1st, 1875, that I would furnish you with a report of my examination of the Consolidated Virginia and California mines on the Comstock lode, at Virginia City, Storey county, Nevada, with my conclusions as to their probable total yield of gold and silver, based upon their present explored extent, and the quality of their ores as ascertained by assays, I would respectfully make the following statement:

My explorations through these mines were accomplished during two prolonged visits, made on separate days—one in company with yourself, and the other under the guidance of the Superintendent. This was a work not merely of a general or superficial character, but of careful and laborious investigation, in which all the galleries and cross-cuts on the different accessible levels were critically inspected and scrutinized with reference to the body of ore that might be within view, and its appearance in point of quality. Having an attendant along who carried bags for their reception, I gathered at frequent intervals, and labeled them, an extensive collection of specimens for assays. The following

Brief Description

Of the position of these mines, which lie in the same general line of ore body that constitute what is commonly known as the "Comstock lode," may aid the mind in forming a better idea of their nature, and will serve to explain the principles which have guided the engineers and Superintendent in laying off the work for exploring their extent and mining the ore. The surface of the whole country around Virginia City is rough, broken and hilly. At this immediate locality there is a long lofty range extension of the Washoe mountains, at places many hundred feet in elevation above the plain, whose steep slope to the valley below faces toward the east, and whose general trend is north and south. About midway up the slope the croppings of the ore of these and of many other mines of the lode are visible.

The First Excavations

Which were made in the early workings here were upon these croppings, but in due time it was discovered that the ore-body dipped toward the east in a measure parallel with the surface of the mountain side, though having no physical nor geological relation to that superficial outline. As a consequence of this discovery, the present shaft, known as that of the Consolidated Virginia mine, was sunk at a point down the slope many hundred feet to the east of its outcropping. It is from this shaft that all the ore from the Consolidated Virginia and California mines has been lifted, until the recent fire, which destroyed the hoisting machinery. The slope of the ore-body of these mines is from forty to forty-seven degrees toward the east, and its trend or line of length is nearly north and south, or in the direction of the line of the containing mountain-like range. This being the relative position of the vertical shaft to the sloping body of ore, it is evident that no ore would be looked for in the descent until several hundred feet had been reached. In point of fact, 1,300 feet of rock were passed through before any horizontal drifting was done to intercept the ore.

Ore of Profitable Richness

Having been met with at this level (the 1300-foot level, as it is called), the shaft was sunk to the depth of 100 feet more, and a similar horizontal drift run in to test the continuance of the ore. Finding that the ore body on the 1400-foot level was undiminished in abundance and richer than that on the 1300-foot level, the shaft was carried down a second hundred feet, with the view to explore a 1500-foot level; and finally, under the encouragement afforded in every foot of descent, a double "winze" has been put down recently in the California mine to a depth of 110 feet below the 1550-foot level. The shafts having been sunk successfully to the depths here indicated, the principle adopted for exploring and probing the extent of ore on each level was to run galleries and cross-cuts. The extent to which this judicious system has been carried is indicated on the four certified maps of the workings of these mines accompanying the statement furnished you by James G. Fair, superintendent of the two mines.

In the brief narrative of the progressive development of the mines above given; it is seen that by this only safe and satisfactory mode of testing the length, depth and width of the ore-body, it has been rendered possible to block out in cubes of a square each the metal bearing mass, so far as penetrated to view, and to thus reach

An Approximate Estimate

Of the probable aggregate ultimate product of gold and silver from these mines; since the maps are constructed to a scale they exhibit clearly the quantity of ore that has been removed from the mines, relatively to the amount that remains untouched, assuming that the system of cross-cuts which penetrate the ore body give correct data for such conclusion. In speaking of these mines they have been referred to here in the language common to both. The line which divides them is only a property boundary, there being two companies, but under one management. The ore is of the

same character, and the east and west walls identical for them both.

The claim of the Consolidated Virginia mine is 710 feet long, and that of the California mine is 600 feet. The explored width of the ore-mass on the 1500-foot level averages 250 feet. The west boundary wall is that of the mountain rock eyenite. The east boundary, which can be scarcely termed a wall, is ferruginous clay. The ore-body itself consists of a semi-crystalline, somewhat granular matrix of quartz, sometimes compact, but more commonly friable and easily crushed, crossed and coated over with whitish clay, containing the precious metals associated with several base metals and a variety of other substances. The nodular and rocky masses scattered through the lode—at times of magnitude to form what is termed a "horse"—is a potash feldspar, and named by the miners porphyry. The following may be stated as the

Composition of the Ore Mass.

Quartz, the largest constituent, constituting the matrix or "gangue;" gold, metallic; silver, metallic; silver glance, or sulphide of silver; polybasite, (silver, copper, iron, zinc, antimony, arsenic, sulphur); stephenite, (silver, copper, iron, antimony, sulphur); blende, (zinc, sulphur); galena, (silver, lead, sulphur); horn silver in small amount, (silver chloride); almina, (as clay); carbonate of lime; sulphate of lime. In this ore the gold is in the metallic state. The silver is metallic and also as sulphide and chloride, and likewise in the complex mineral forms above named. The iron, copper, lead, zinc, antimony and arsenic are in a condition of combination with sulphur as sulphides of those metals. The silica and clay are simply in mechanical association with the above. At the works of the mines, as well as at the mills, all the ore delivered is sampled as fairly as possible, that the averages may be obtained for assays for the purpose of adjusting the accounts between the mines and the mills. With the data in our possession and the maps before me I may venture upon the following calculations and estimate the

Total Ultimate Product

Of the gold and silver of the ore body of these two mines: On an inspection of the official surveys exhibiting the galleries and cross-cuts, it would seem fair to conclude that with proper allowances the ore body equals an amount which, taken at the actual assays, would give as the ultimate yield of the two mines, \$300,000,000; but to guard against a chance of over-estimating, I take the assays at one-half that ascertained, which will place the production at not less than \$150,000,000. With a view to make due allowances for interruptions to the continuity of the body of ore which lies between the 1500 and 1400-foot levels, the whole of the ore contained between the 1400 and 1300-foot levels is thrown in, and not embraced in the estimate. It may also be stated that the very promising ore developments below the 1550-foot level, the assays of which run very high, have also been omitted from my calculations. All of which is submitted by,

Very respectfully, your obedient servant,
November 15th, 1875. R. E. ROGERS.

Rainfall.

A London paper says: "In the Paris *Bulletin International* for June 30th last, Professor Raulin, of Bordeaux, gives the results of an examination of a comparison of the gross amount of the rainfall for the ten years, 1851-60, with that for the ten years, 1861-70, from which it is shown that, as regards the southern half of France, the rainfall during the former of these decennial periods exceeded that of the latter at forty-six out of the fifty-three stations at which observations were made for twenty years. A similar distribution of the rainfall during those two decennial periods appears to have taken place, with few exceptions, over a large area, embracing the British Isles, France, Germany, Italy, Spain, the basin of the Mediterranean, and Algiers. The point is an interesting one, and we hope that meteorologists will inquire how far the rainfall observations of their respective countries agree with the result obtained by Professor Raulin for the southern half of France."

Such facts as these go to show how little is known of meteorology and its laws. Most of our newspapers have had much to say of late years about the connection of forests with rainfall. That there may be some trifling influence in favor of more rain with more trees in some cases is possible, but here we have an average increase of rain in a decade from a part of the world which in the same time would show a decrease of woodland. Woodland naturally exists to the greatest extent in those countries where the precipitation of moisture is favorable to the ripening of seeds and their subsequent germination. The woods are a consequence, not a cause, of the moist climate. But the fact of the rainfall in comparison with wood-clearing being found at one time to favor a denudation theory, and at another time to oppose it, should be evidence that there is little connection between the two.—*Forney's Weekly Press*.

SAVE HEAT.—Our economical readers should remember that the surplus heat wasted from a common stove will, if conducted through a drum into another room, warm the room as much as a small stove would, and will compel the fuel to do double the duty and give double results.

Quicksilver Product.

It is well known that the production of quicksilver has been largely increased in California during the past few months. The following statement, furnished by a correspondent of the *Bulletin*, will show what one of the leading quicksilver companies has accomplished during the past year:

The Redington quicksilver company, during January, February and a portion of March, 1875, were not producing quicksilver, being engaged in adding to and changing their reduction works. In March they got their reduction works well under way again, and their reduction for the current year ending December 31st, 1875 (say ten operative months), has been 8,080 flasks of quicksilver. Since September last their production has been upwards of 1,000 flasks per month, at which figure it closes the year. This increase of product is in a great degree due to the marked success of two new furnaces for the reduction of fine ores or Tierras. These furnaces are the invention of the superintendent of the company, Charles E. Livermore, and they may safely be said to introduce a new element into quicksilver reduction, making it possible to profitably utilize material largely produced by all quicksilver mines, but heretofore handled, always at no profit, and frequently at an absolute loss. The Redington quicksilver company have now in active, continuous operation four of the Knox & Osborne patent furnaces, and two of the Livermore patent fine ore furnaces, their total reducing capacity being upwards of 120 tons of ore per day. This large quantity of ore is easily yielded by the upper levels of the mine, none having yet been drawn from below the 200-foot level. The mine has, however, been opened by shaft to the depth of 400 feet, and consistent prospecting work is maintained in advance, so as to insure a supply of ore for at least two years ahead of requirements. The company employs 300 men in its various departments, and has very extensive works, the whole affording a most striking example of what careful management on a strictly business basis will accomplish. Such results have been attainable by reason of the fact that the management of the mine has been carefully attended to by the comparatively few individuals who own it, and the property though incorporated as a stock company, has never been on the stock market for sale or speculation, but has always been handled as a legitimate operative business. It has, during the past year, enjoyed a profitable contract with Messrs. Flood & O'Brien to supply them with 500 flasks per month, and this contract is still in force. The capital stock of the company is \$1,260,000, in 1,260 shares of \$1,000 each, and regular monthly dividends of \$30 per share have been paid thereon during 1875, or \$37,800 per month, making a total of \$453,600 divided profits for 1875. Besides this, about \$125,000 has been invested in new land purchase, buildings, machinery, new reduction works and other appliances, adding largely to the value and future productiveness of the property.

Eureka Bullion for 1875.

Our mines and smelters have been doing extremely well the past season, and are still looking and yielding better than at any previous time in the history of the district. From Mr. Hill, Wells, Fargo & Co.'s agent at Palisade, we learn that there have been shipped from here during the present year 22,124,146 pounds of crude bullion. This is exclusive of the refined bullion forwarded by the Richmond company, and which must have aggregated a very considerable sum, though we have not the exact figures. Our principal mines are the Eureka Consolidated, Richmond, K. K. and Atlas, and nearly all of the vast quantity of bullion noted above came from these mines. The largest shipment was made in July, amounting to about 3,000,000 pounds. During the present month, up to the 18th, the shipments aggregated 1,687,876 pounds, which is considerably in excess of shipments for the same number of days for any prior period. It will be seen from these enormous figures that Eureka is on the high road to a great and lasting prosperity. With the advantages furnished by the construction of the Eureka and Palisade railroad we shall expect our bullion product to be nearly doubled in 1876. Eureka rests on a solid foundation, and, to our notion, a brighter future awaits her than any other mining town on the Pacific Coast.—*Eureka Sentinel*.

A HINT TO MINERS.—Quartz and gravel, as well as placer, worthy of thought and action, is contained in the following, clipped from the *Placer Herald*: Trueh & Bellard laid out a portion of their placer claim as a fruit garden. They planted some 300 or 400 trees of various kinds, and also strawberry and gooseberry plants. Possessing first class irrigating facilities the garden has thrived surprisingly. The strawberry bushes have yielded an abundance of fruit during eight months of the year, while the trees have grown rapidly. Next season it is expected that most of the trees will bear fruit. In a similar way nearly all our foothill slopes may be covered with beauty. A short time ago the plot of ground to which we have referred was as barren looking as the rest, but a small stream of water has proved the soil to be fertile in the extreme.

HIGH VELOCITY OF WIND.—The Signal office at Mt. Washington recently reported a wind velocity of 156 miles per hour. This is the highest velocity recorded at that station.

Prizes in Industry and Agriculture.

The Societe d'Encouragement of Paris has recently published its list of prizes offered from 1876 to 1881, both inclusive. It may be mentioned that this society bestows annually a gold medal bearing the likeness of some man who has achieved a high reputation in art or science, or is the originator, whether French or foreign, of works which have exercised the greatest influence on French industry during the six preceding years; in 1873 this grand medal was awarded to our own countryman, Sir Charles Wheatstone.

Although all the subjects are open to foreigners as well as natives of France, many would of necessity be confined to the latter. The following items from the long list are likely to have an interest in this country:

A prize of 200 francs is offered in 1880 to the author of the most important improvements in the material and processes employed in civil engineering, architecture and public works.

A prize of 2,000 francs is offered in 1879 to the inventor of a machine for combing short staple cotton which has been brought into practical use.

A prize of the same amount is offered for 1880, for a machine for cutting files of all kinds automatically, and which shall have worked for at least three months.

A prize of the same amount is proposed to be awarded in 1877 for the invention of any efficient means of stopping the vibrations caused by steam hammers, and other tools acting by percussion, from being propagated beyond the works in which they are employed.

Prizes of the same amount are offered in 1878 and 1879 for the industrial application of oxygenated water, and for the economic preparation and application of ozone; and in 1876 for fixing the nitrogen of the atmosphere in the form of nitric acid, ammonia, or cyanogen, the object being to obtain practically some compound of nitrogen cheap enough to use in making manure from the nitrogen of the atmosphere, to the exclusion of animal matter.

A prize of 6,000 francs is proposed for 1878, for a theory respecting steel, founded on actual experiments, and resulting in improved means of directing the manufacture of steel.

A prize of 3,000 francs, set down for 1880, for the disinfection of the residue from gas works.

One thousand francs are offered in 1880, for an apparatus capable of producing high temperature in home workshops rapidly and economically.

A prize of 2,000 francs is announced for a method of preventing soot adhering to chimneys so that they may be completely and easily cleaned.

All memoirs, models, etc., must be lodged with the secretary of the society before the 1st of January of the year in which the prize is to be awarded. Full particulars will be found in the August number of the *Bulletin* of the society, which is in the reading room of the society of arts.—*Journal Society of Arts*.

Damages from Hydraulic Mining.

An adjourned meeting of citizens of Sutter and Yuba counties was held at Marysville, Friday afternoon, to consider the effects of hydraulic mining in the mountains upon the plains below, and to consult and advise as to what remedy can be had. The meeting, says the *Appeal*, was largely attended, and by many of the most prominent farmers and citizens in the two counties. The grievances of the people, present and prospective, were presented and contrasted, and the more the matter was investigated the more perplexing and difficult the remedy appeared. Various expedients were suggested, and no individual present was prepared to advise the best course to adopt. All could plainly see that hydraulic mining was destroying property a thousand times more valuable, but how could it be stopped? As one speaker said, who present here among the sufferers has the moral courage to say mining shall be stopped? The mining interests of the State are large, and are owned principally in the cities. To ask the legislature to destroy it will arouse the opposition of the owners. Turn the matter as we may, and look at it from the valley or mountain standpoint, and we find it is beset with the greatest of difficulties. If any single miner runs tailings upon a farm below, the owner of the mines is liable and could be made to pay damages. But the damages we complain of is caused by thousands of miners, and has been going on for over twenty years. Who shall we sue or prosecute under a penal law? The action of the meeting finally culminated in the appointment of a committee to draft a bill to be presented to the legislature, making it unlawful to throw mining debris into Bear river, Yuba river or Feather river, or their tributaries, and making any and all hydraulic mining companies so flowing debris in said streams answerable in proportion to the amount so thrown into said streams for the damage caused thereby. Also, to ask the legislature to investigate by appropriate means this subject, in order that some plan may be adopted by which the destruction occasioned by hydraulic mining on said streams may cease. And to ask the Federal government for appropriations to keep open for commerce the navigable streams of the State rendered unnavigable by hydraulic mining. The meeting adjourned till Saturday, January 8th, at twelve o'clock, to hear the report of the committee and take action thereon.

USEFUL INFORMATION.

A Novel Device.

In Northern cities, where the cold is severe, serious annoyance and no little danger often occurs from the freezing of water pipes. The *Scientific American* enters the following word of caution, and describes a very ingenious device for meeting such emergencies:

When a pipe from the street freezes, the range fire should be at once extinguished, as otherwise the water back will either blow up or be burnt out; in the former case serious damage is possible. Last winter the plumbers dug up the streets, and built fires over the supply pipes, and went through other operations, which generally resulted in a bill of from eighty to one hundred dollars. At the present time, if an invention which we recently examined proves as useful as appearances indicate, the cost of such proceedings will be greatly reduced. The apparatus is a small steam boiler, heated by a pan of charcoal beneath it. The hot water—not steam, as in this machine a constant supply of water against the ice is found to thaw the same quicker, paradoxical as the fact may appear—is forced into a small rubber tube, the end of which has a metallic tip, and around which stout copper wire is spirally wound. This wire is held in a coil in a rotating wire cage, and freely unwinds as it is pushed into the pipe. When the end meets the ice, the pushing by hand is stopped, but is continued by an ingenious spring arrangement. By the spiral wire the tube is literally screwed into the ice, which is softened and melted before it by the continual stream of hot water issuing from the end of the pipe.

We might add that there is still an excellent field for invention in other devices of the same description; and at the same time we might suggest, to inventors already in possession of similar patented apparatus, that now is the time to bring them to the notice of the people.

THE ORIGIN OF MAHOGANY FURNITURE.—The facts regarding the first introduction of mahogany as material for furniture, though long known, are not the less interesting: A physician of the name of Gibbons, who resided in London, received in 1724 a present of some mahogany planks from his brother, a West India captain. Dr. Gibbons was then building a house, and he desired his carpenter to work up the wood. The carpenter had no tool hard enough to touch it; so the planks were laid aside. The doctor's wife, after the house was finished, wanted a candle box, and the mahogany was again thought of. A cabinet maker of the name of Wollaston was applied to; and he also complained that his tools were too soft. But he persevered, and the candle box was at length completed—after a rude fashion, no doubt. The candle box was so much admired, that the physician resolved to have a mahogany bureau; and when the bureau was finished, all the people of fashion came to see it. The cabinet maker procured more planks, and made a fortune by the numerous customers he obtained. From that time the use of mahogany furniture went forward among the luxuries; and the drawers and bureaus of walnut tree and pear tree were gradually superseded in the houses of the rich.

EBONITE.—The use of ebonite, one of the newer preparations of india rubber, is constantly increasing, on account of its better applicability to many purposes in the arts than its near ally, vulcanite. The two substances are quite similar, being composed of india rubber and sulphur, with some preparation of gutta percha, shellac, asphalt, graphite, etc., although these latter are not essential. In vulcanite the amount of rubber does not exceed twenty to thirty per cent., whereas in ebonite the percentage of sulphur may reach as high as sixty. An increased temperature is also required for its preparation. The approved formula consists in mixing together one hundred parts of rubber, forty-five of sulphur and ten of gutta percha, with sufficient heat to facilitate the combustion. In manufacture, a sufficient quantity of this mixture is placed in a mold of a desired shape, and of such material as will not be affected by the sulphur contained in the mass. It is then exposed to heat of about 315° and a pressure of about twelve pounds to the square inch for two hours. This is done most readily by placing the mold in a steam pan, where the requisite pressure and temperature can easily be kept up. When cold, the ebonite is removed from the mold and finished and polished in the usual manner.

A new method of warming first-class carriages in express trains has been adopted in Bavaria. A special van is attached to the train, and contains a powerful "calorifere," and the heated air is conveyed to all the carriages of the train by means of india rubber tubes. The experiment with first-class carriages is reported upon so favorably that the authorities have determined to apply it to all the carriages on the Bavarian line, and it is expected that it will soon be adopted on all the German railways.

ROSIN.—Common rosin, the non-volatile portion of crude turpentine, was originally termed "colophony," from Colophon, in Ionia, where rosin was first produced by the ancient Greeks. It is sometimes so called in the present age.

PRACTICAL SPIRITUALISM.—Dr. E. P. Miller, an intelligent physician of New York, has become an avowed and ardent advocate of the "spirituality" of the Eddy tricksters of Vermont. The doctor is so certain of the heavenly power of one of the Eddy female performers that he has publicly offered a challenge or test exhibition, under a wager of \$5,000, that her "manifestations" are genuine, and agrees to leave the matter to the decision of a committee of twelve persons, to be mutually chosen by himself and the acceptor of the challenge. Mr. W. Irving Bishop has accepted the challenge, undertakes to prove that the woman is a fraud, and further, agrees to reproduce all the "materializations" and "manifestations" that she may produce, without any spiritual assistance whatever. He says he has been to Vermont and learned the art completely. He suggests that \$5,000 shall be deposited by each party, the winner to donate that amount to some designated charitable institution. The result of the contest, if it comes off, will be interesting, however it may eventuate.

SHARPENING EDGE TOOLS.—Very few general amateurs have sufficient practice to acquire, or to retain when acquired, the knack of producing perfectly flat facets on their plane-irons, chisels, etc. By the aid of the following simple contrivance, put together very easily, the end may be attained with dispatch and certainty, the shavings leaving the plane with the real professional "whistle." A simple saddle of wood, with a thumb screw and clamp, or dog, for fixing the tool firmly to the work bar. The oil-stone is placed between the cheeks and the tool, so adjusted that the saddle bears with its heels or hinder angles on the bench, the tool, of course, bearing on the oil-stone. The saddle, and with it of course the tool, is then worked backwards over the stone.—*Ex.*

SCREW THREADS.—The thread on a three-eighth inch gas pipe will sustain a weight of 5,000 pounds; on a half-inch pipe, 7,000 pounds, and on a three fourth inch pipe, 9,000 pounds. These facts are important to persons engaged in baling chandeliers, etc.

AQUAFORTIS, applied to the surface of steel, produces a black spot; on iron, the metal remains clean.

GOOD HEALTH.

Longevity.

We are too apt to sneer at the story of such characters as the Count St. Germain and the Baron Munchausen, and Aladdin—they are improbable, as the world goes. But let mankind heed the true laws of hygiene, and it will not be seldom, but frequent, that we shall have to note longevity as great as that attributed to St. Germain. It was common for him to relate the actions, conversation, even to the imitation of the peculiarities of voice, of people that had been dead fifty years, and no one was ever able to account for these incomparable delineations except upon the hypothesis of contemporaneous and actual witness. It is well known that St. Germain would never eat the elaborate dishes prepared for the tables of the courts where he was so frequently a guest, and seldom tasted wine. Although rich, having plenty of servants and the finest diamonds and jewelry, his fare, so far as could be ascertained, for his life was a constant mystery, was composed of oat meal, groats, and some times the white meat of chickens.

In the travels of the writer in the far East, and in intercourse with the old rosicrucians or modern alchemists, it was observed that their diet was abstemious, and composed chiefly of fruit and grains. Even among cannibals the old doctors had every appearance of being in some instances over an hundred years of age. It was noted that these old men never indulged in the orgies they were invited to, but sat or stood as spectators. It is so hard for man to study his own true nature, and it is only grain by grain that the great truths which lie at the foundation of long life and happiness can be gathered.

We are rushing with such lightning speed, in this fast age, that the study appears to be how to condense the whole sum of existence into as few years as possible—or that is the result, for the vital force present is only a positive sum; and if man's life be a rocket, it must be expected that it will be correspondingly short. Every instinct is suggestive of self-preservation, but the philosophy of the nineteenth century is contained in one line: "A short life and merry." F. M. SHAW.

Los Angeles, December, 1875.

CARE OF THE GUMS.—Those troubled with ordinary diseases of the gums should wash their teeth night and morning with a moderately small and soft brush. After the morning ablution, pour on a brush, slightly dampened, a little of a lotion made by mixing one scruple of carbolic acid, rectified spirits of wine two drachms, and six ounces of pure, or distilled water.—*Lancet.*

Mr. GEORGE R. LABAU, 111 years old, as distinctly shown by the records of his christening, attended the State fair at Easton, Pa., last week. The old man is talkative and intelligent, has a fine cheek, shows little emaciation, and can do considerable work without fatigue.

Prevention and Cure.

It is astonishing, to say the least, that everywhere "cure" is recognized before prevention. The old adage "an ounce of prevention is worth a pound of cure," seems to have been forgotten, or at least disregarded by the mass of humanity. Men will search throughout the range of the whole pharmacopoeia, and cast about them all their lifetimes for some chemical or vegetable compound which shall be an effectual cure for some of the "ills which flesh is heir to," while if they should spend half the time in looking for the cause and prevention of this disease, the sufferings of humanity would be mitigated to an incomparably greater degree. And when such a medicine is found, it very seldom affects a cure. Even when the cause and prevention are known, men seem to overlook the fact that the suffering consequent upon the exertion and self-denial necessary for prevention of disease is less than that which follows the neglect to apply the preventive. This substitution of cure for prevention seems to hold precedence where civilization is highest to a greater degree than among less enlightened nations. And why is this? Among barbarous nations more attention is paid to prevention, and the few remedial agents used are simple, and seldom effectual in themselves; whereas, in civilized countries the greater knowledge of science induces men to search more extensively for new and better curatives, and as more and more scientific discoveries are made, the medical field becomes wider and wider. And thus, in this rush after new medical discoveries, the laws of prevention of disease have been overlooked, and left far behind.

Now, viewing this matter as one of the greatest importance to the human family, the next step is to consider how it may be brought to the attention of the mass of the people. The medical men, as a class, do not do it, although it is their legitimate business, because it would not be for their pecuniary interest. But there is one other resource, and one which is adequate to the task. Let the press take hold of the work, and after clearing its pages of all medical advertisements, in their place let it elucidate the common rules and principles of health, and point out the causes of sickness and disease and the methods of prevention, and by so doing it would lose nothing, pecuniarily or otherwise. Let this be done, and the day is not very distant when the swindling practice of the multitude of quacks with which the country is swarming will be at an end, and the people, stronger, both physically and mentally, will adopt for their motto, "moderation in all things."—*Cor. Pnenological Journal.*

BORAX IN COLDS.—A writer in the *Medical Record* cites a number of cases in which borax has proved a most effective remedy in certain forms of colds. He states for a sudden hoarseness or loss of voice in public speakers or singers, from colds, relief for an hour or so, as by magic, may be often obtained by slowly dissolving and partially swallowing a lump of borax, the size of a garden pea, or about three or four grains held in the mouth for ten minutes before speaking or singing. This produces a profuse secretion of saliva, or "watering" of the mouth and throat—probably restoring the voice or tone to the dried vocal cords, just the same as "wetting" brings back the missing notes to the flute, when it is too dry.

TO OBSOURE SCARS.—To obscure, hoil in three quarts of water one pint horseradish, four ounces pulverized alum, and four ounces rock salt. When cold, wet pieces of thick lint therewith, and apply frequently. This will harden and thicken the skin. Persevere for some time, and the effect is certain. On going among friends, dull the shiny appearance by bathing it with a little spirits of hartshorn in water. The first named preparation is best when made newly; it gradually loses pungency and effectiveness, and so when weak must be renewed. With time and care, as above, the redness and peculiar appearance of scars will largely diminish. The person should carefully avoid all irritation of the parts.

BUILDING GROUND.—We want more of a dry earth system. Perfect under-drainage is the first great need of most cities and large towns. Regulations of cellars, and of all other holes below the surface, is the next great study. The proper airing of all sub-structure, because of its proximity to the ground, comes in next for consideration. What can we do to sweeten or purify surface-soil already formed, is another point. The great question of what to do with all refuse so as to keep it out of city soil is the large and momentous subject which must ever present itself to our attention.—*Public Health Association.*

LOOK TO YOUR HEALTH.—Pay but half the attention to the condition of your lungs that you do to the condition of your purse and you will not only prolong your own days, but your children will inherit that from you over which there will be no wrangling, no strife, no false swearing; a treasure divided by nature's own hand, in which your sons and your daughters, the eldest and the youngest, shall "share and share alike."

A FATAL KISS.—The *Albany Argus* says that Miss Kate Noyes, of Lausburg, is in a critical condition from poison, arising from kissing her deceased niece, who died of diphtheria. The young lady had a slight sore on her lip at the time. A swelling commenced in her lip, which soon extended to the nose, and it is feared the difficulty will reach the brain.

DOMESTIC ECONOMY.

The Art of Frying Fish.

Several kinds of fish are fried when small, such as small trout or troutlets, carps, tench, sun fish, pike, pickerel, flounders, white-fish, black and blue fish, perch, porgy, weak-fish, herring, bass, and the like, and smelts, which never grow above the frying size.

When fish or anything else is cooked in a frying pan with just fat enough to prevent it from burning, it is not fried but *sautéed*, there being two very distinct ways of frying. To fry means to cook fish or something else immersed in hoiling fat. To *sauté* means to cook fish or something else with just fat enough to merely cover the bottom of the pan; for instance, small fishes are fried, but omelets are *sautéed*; potatoes are fried, but parsnips are *sautéed*.

Many inexperienced cooks make mistakes on that account; they read in some cook-book that such an article of food is good fried, and set to frying it when it should be *sautéed*, and vice versa.

The fat skimmed from the surface of broth, which is beef-suet, the trimmings of steaks or roasting pieces of beef melted as directed below, are better for frying purposes than lard, not flying all over as lard does.

The fat skimmed from trimmings or from around the kidneys of beef is cut in small pieces, put in an iron pot, and set on a rather slow fire. As soon as it begins to melt, ladle off the melted part and turn it into a stone or crockery jar, which you cover when cold. Put it away in a cool, dry, and dark place. A careful cook never needs lard for frying purposes, but has always more fat than is necessary out of hoiling or roasting pieces, and that skimmed on the top of broth, sauce, and gravies. Some cooks will not take the trouble to melt it when the mistress allows as much lard and butter as is asked for.

It is an error to believe that by using much fat to fry, the articles fried will taste greasy; if there is not fat enough in the pan to completely immerse the objects fried, they will certainly taste greasy. It will be the same if the fat is not heated enough. It is heated enough when jets of smoke ooze out of it, or when, on throwing drops of water on it, it makes a crackling noise.

When the fat is hot enough, the article that is to be fried is dropped into it, and stirred gently now and then with a skimmer. When done, it is taken off the pan with a skimmer and turned into a colander, which should rest on a dish or bowl to receive the fat that may drop from it.

If the article to be fried is not completely immersed in the fat, the part not immersed will absorb fat, and, as stated above, will be greasy; but if there is fat enough to cover it entirely, the intensity of the heat closes the pores, carbonizing the exterior of the article, as it were, and preventing it from absorbing any fat.

If the articles to be fried be tender and somewhat brittle, they are put in a wire basket or perforated double bottom made for that purpose, and the basket is plunged into the fat. The basket is raised when the articles are fried, and held over the pan to let the fat drop; they are then taken carefully out of it, placed on a dish, sprinkled with salt, and served hot.

When the frying is done, the pan is put away for a few minutes, to allow the particles of solid matter that may be in to fall to the bottom of the frying-pan; then it is turned into the jar, gently and slowly, so as to retain those particles in the bottom and it is put away for another time.—*Prof. Blot.*

TO PRESERVE BREAD FOR LONG PERIODS.—Cut the bread into thin slices and bake it in an oven, so as to render it perfectly dry. In this condition it will keep good for any length of time required, and without turning moldy or sour, like ordinary bread. The bread thus prepared must, however, be carefully preserved from pressure, otherwise, owing to its brittleness, it will soon fall to pieces. When required for use it will only be necessary to dip the bread for an instant into warm water, and then hold it before the fire till dry, after which butter it, when it will taste like toast. This is a useful way of preserving bread for sea voyages, and also any bread that may be made too stale to be eaten in the usual way.

FRENCH PANCAKES.—Half a pint of milk, two ounces of butter, two ounces of loaf sugar, two ounces of flour, two eggs. Put milk, butter and sugar into a saucepan to dissolve (not hoil), beat eggs and flour together till quite smooth, then add the other ingredients and mix well. Divide this quantity and put it in four saucers to bake for twenty minutes; lay two pancakes on a dish, spread preserves over, and cover with the other two pancakes. Serve hot.

OXFORD DUMPLINGS.—Mix well together the following ingredients: Two ounces of grated bread, four ounces of currants, four ounces of shred suet, a tablespoonful of sifted sugar, a little salt, and plenty of grated lemon peel. Beat up well two eggs; add a little milk and divide the mixture into five dumplings. Fry them in butter a light brown color and serve them with sauce.

CRISP MUFFINS.—One pint of sifted Indian meal, one pint of milk or cream, two eggs, a teaspoonful of salt, a spoonful of butter or lard. Drop the batter in a hot, greased pan or oven, by spoonfuls, taking care that your muffins do not touch. Let them bake till crisp and brown.

POPULAR LECTURES.—The winter course of popular lectures, under the auspices of the University of California and the Mechanics' Institute, commences on Saturday evening next, at the hall of the Institute, on Post street. The course of lectures will be as follows: January 8th, 1876, "Trade Tuition," by A. S. Hallidie; 15th and 22d, "Coral Reefs and Islands," by Prof. Jos. Le Conte; 29th, "Wet Processes in Metallurgy," by Dr. G. F. Becker; February 5th, "Recent Researches on the Lunar Surface," by Prof. F. Soule, Jr.; 12th and 19th, "Domestic Beverages of Different Nations," by Prof. E. W. Hilgard; 26th, "Socrates," by Prof. G. W. Bunnell; March 4th, "Solar Protuberances," by Prof. F. Soule; 11th, "The Metric System," by Prof. John Le Conte; 18th, "Heat—Engines in connection with the Mechanical Theory of Heat," by Prof. F. G. Hesse; 25th, (Subject to be announced), by Prof. W. Ashburner.

The water in the Savage mine is drained down to the 2200-ft level, at which point it is easily held by the pumping machinery, and preparations are being made to resume work in the drifts and winzes on that level in a very few days.

It is expected that the prospecting of the West Belcher mine several hundred feet below the tunnel will be commenced through the old Overman shaft in a very short time.

The Raymond & Ely mine, during the four days ending last week Tuesday, shipped to the mills at Bullionville 349 tons of ore, the largest shipment being made on Sunday—97 tons.

The Mining Debris Question.

A mass meeting of the farmers has been held recently in Marysville, to consider the matter of the damages done to the farms and rivers by the deposition of debris from the mines. The question is one which by the greatness of the interests involved demands careful study and just action. It is sound, as a general principle, that the industries of men should be so adjusted that they may advance evenly and without working hardship and detriment to each other. The way to effect this adjustment is often difficult to determine. No action should be urged hastily or without careful weighing of all the considerations involved. The study and research necessary to wise action should not be shrunk from, because upon wisdom in matters of this kind depends the symmetry and endurance of our industrial growth.

A committee is now at work drafting a bill, to be presented to the legislature in a few days, making it unlawful to flow mining debris into Bear river, Yuha river or Feather river, or their tributaries, and making any and all hydraulic mining companies so flowing debris in said streams answerable in proportion to the amount so thrown into said streams for the damage caused thereby; also, to ask the legislature to investigate by appropriate means this subject in order that some plan may be adopted by which the destruction occasioned by hydraulic mining on said streams may cease; and to ask the Federal government for appropriations to keep open for commerce the navigable streams of the State rendered unnavigable by hydraulic mining. This matter will bring about an exciting debate, for it is a big question to wrestle with, and a powerful pressure will be brought to bear to bring about some sort of legislation this season.

We must confess we do not see any way out of the difficulty ourselves. It is unjust to the property owners of the valley to yearly destroy their crops by the overflow; but it is also unjust to expect miners to close their cabins. The miners were there first and claim the first right. The only solution to the problem we have seen is that offered by Mr. Miller, of Nevada county, who wrote a series of communications to the Nevada Transcript on this subject, last year.

He proposes that the desired end shall be obtained by constructing reservoirs in some of the innumerable small osons and hollows among the mountains—places which are wholly useless for any purpose whatever, at present, and which would actually be utilized by the process suggested. Into these natural tanks or reservoirs the flumes and ditches should be emptied. There the waters would rapidly deposit their heavy detritus, and thence they could be reconducted to the rivers by convenient waste-weirs and sluices. In a few months the first series of reservoirs would be filled up, and the ditches could be conducted to fresh localities; but in drawing off the waters some acres of soil would be found deposited, and would afford the basis for cultivation. In this way the proceeds of hydraulic mining, instead of inflicting damages and destruction upon the valley lands, would gradually enlarge the cultivable area in the mountains, and by repairing the effects of systematic denudation by monitors and little giants, might even tend to restore the climate equilibrium at present so seriously threatened by the processes being carried on throughout the mining regions.

The Territorial Enterprise also favors the same thing, in the following, which appeared in its Saturday's issue: "There are in the foothills of California many millions of acres of land unfit for cultivation. The bed-rock is close to the surface, making the land of no use to the husbandman. The rivers should be dammed high enough in the hills to turn their streams upon these worthless lands, and reservoir succeeding reservoir should be built until the waters running from one to the other become clear enough to turn back into their original channels, or better still to be conducted to become a blessing to the land where they now are a curse. This is a great work, but its cost can be estimated, while the damage being done even now by the debris cannot be estimated. The two questions—to provide for water for the lands in the valley and to provide against the destruction because of the debris being carried down by the water—are presented together to the present California legislature. The remedy for both evils is the same. The duty is plain. The only question is how to proceed."

It is proposed to attach that portion of Dakota territory which includes the Black hills to Wyoming, thus making the 103d degree of latitude the eastern boundary line of Wyoming and providing as a natural line the eastern base of the Black hills, for the convenience of the settlers in the transaction of legal business.

The town of Munroe, in Tom Payne district, 200 miles south of Ogden, in the Sevier basin, has a mining population of 500, and yet the camp is but three months old.

In Weaverville, up to the 1st instant, twenty-seven inches of rain had fallen, besides some snow. The miners are delighted.

The mortgage tax question has not yet been decided by the Supreme Court. The case is to be argued on the 12th inst.

The Idaho Mine.

The Idaho mine, Grass Valley, has for the past seven years paid dividends regularly, and has been looked upon as one of California's prosperous mining properties. This year, although eleven dividends were paid, the yield per ton has not been so large, nor have the dividends amounted to so much. The present yield gives very little margin for profit, and the president and superintendent of the company say that any further falling off would be a reduction of dividends. During the year 1875, they crushed 28,103½ tons of rock, of which 6,828½ tons came from the 500 level; 2,096 tons from the 600 level; 10,554½ tons from the 700 level; 8,485½ tons from the 800 level; and 139½ tons from the shaft and 900 level.

This gives a total yield of 27,318 68-100 ozs. million.

147 tons sulphur..... \$478,073.36
Tailings..... 8,936.44
Specimens..... 7,946.98
Old copper plate..... 112.60
Total..... \$496,669.38

Yield per ton..... \$17.63

The report of the secretary of the company, Geo. W. Hill, as published in the *Boothill Tidings*, gives, with regard to the dividends of the mine, some interesting figures. The receipts from all sources for the fiscal year ending December 6th, 1875, \$492,925.28, which added to balance on hand show assets for the year to have been \$509,430.72. The total expenses including dividends for the year, were \$505,194.66. The dividends were eleven in number, and amounted to 55½ per cent. on the capital stock, or \$172,052. There was no dividend in November, and but \$3 per share instead of \$5 in December. The failure to declare a dividend on both of these occasions is attributed to the suspension of the former treasurer, Mr. Thos. Findley. The Secretary presents in an epitomized form the aggregate receipts and expenditures of the company for the last seven fiscal years, that being the period in which the mine has paid dividends, and before which only prospecting was done.

1869..... \$ 306,088 76
1870..... 183,450 23
1871..... 407,801 16
1872..... 404,035 52
1873..... 1,010,612 20
1874..... 669,023 03
1875..... 492,919 27

Total receipts for seven years..... \$3,473,380 16
There has been paid out in dividends as follows:

1869, 11 dividends, aggregating 55 pr. ct., \$ 170,500 00
1870, 7 " " " 12 " " 37,200 00
1871, 7 " " " 76 " " 232,600 00
1872, 11 " " " 52½ " " 162,750 00
1873, 12 " " " 220 " " 632,000 00
1874, 12 " " " 102½ " " 317,750 00
1875, 11 " " " 55½ " " 172,050 00

Being 76 dividends, aggregating 672½ per cent. on the capital stock, amounts to..... \$1,774,750 00

The president and superintendent of the mine, Edward Coleman, gives a detailed report of operations in the mine, from which we condense what is of general interest. A fire-proof building has been erected over the pump-shaft and machinery.

In regard to the underground work, the drifts have been kept well ahead of the stopes, and the mine may be considered in good working order throughout.

The 500 east hacks are worked through the 400 level a distance of 144 feet from the shaft, and there still remain about 300 feet in bottom of the 400 level to work out. The 500 east level is in 371 feet from the shaft, and there still remain about 225 feet to go before exhausting the pay chute. The 600 east hacks are about all worked out and a few months more, with a small party of men, will entirely exhaust them. The 600 west hacks are also entirely exhausted. The 600 east level is in 1,344 feet from the shaft, the last 555 of which have been either through worthless quartz or barren ground. As this drift is in further from the shaft than any other and there is still a distance of 1,257 feet to the eastern boundary, it is thought best to continue this drift on as fast as possible, with the view of prospecting that part of the claim. The 700 west hacks are all worked out, with the exception of a small piece next to the western boundary. The 700 east level is in 712 feet from the shaft, and is still in pay rock; and the hacks are worked through to the 600 level 375 feet from the shaft, and there are still remaining about 394 feet to work out in the bottom of the 600 before exhausting the pay chute. The 800 west level is in 356 feet from the shaft, the last 150 feet of which have been in rather a small ledge and low grade ore, and the hacks are worked through to the 700 level 35 feet from the shaft. The 800 east level is in 388 feet from the shaft. The ledge is quite large the full length, and the backs, also, are in a good sized ledge. It is not worked through to the 700 level at any point.

The ledge in the shaft is of good quality and well defined from the 800 down to about 60 feet below that level; the hanging wall then goes down very flat, and the ledge becomes broken up and makes into several stringers. The shaft was continued down on the same angle as before, 51½ degrees, and after sinking 120 feet from the 800 level a cross-cut was run in, and after drifting 59 feet the hanging wall was struck, but no quartz was discovered. A drift was then run east on one of the stringers; it is now in 137 feet from the shaft, with a good sized ledge in the last 10 feet; but it is not next to the hanging wall, and the quartz is of a low

grade, although showing some gold; and we have good reason to hope it will improve as it is continued east.

In looking over this statement, it will be observed we have a large amount of quartz in sight (but not broken), and as the 700, 800 and 900 levels are still in pay rock, it is impossible to give an opinion as to the amount of pay rock we may expect to take from the mine—but I have no doubt it will last for several years.

The mill and mining expenses were as follows, for the year:

Surface labor..... \$ 45,345 63
Underground labor..... 144,186 89
Wood and poles..... 24,829 60
Hardware..... 4,646 16
Drill steel..... 1,787 90
Powder and fuse..... 4,664 05
Candles and oil..... 4,503 76
Lumber..... 2,146 08
Foundry..... 8,023 89
Coal..... 1,969 01
Quicksilver..... 1,932 87
Superintendent's salary..... 6,000 00
Sundries..... 3,027 82

Total..... \$264,863 66

Average cost per ton..... \$9 06½
Other general expenses bring the total expense for the year up to \$300,647.98. There is yet the sum of \$32,490.68 due the company from Thomas Findley, its former treasurer.

Is the Fryer Process a Success?

A correspondent of ours who is traveling through the mining districts says the above question is the most frequently asked among the quartz miners, and very much interest is manifested in it. He writes as follows:

So far the public, as such, have not been permitted to see the workings of the new process; but yet those most anxious for improved milling success, say they believe certain results are evident, and that they are accomplished without battery, pans or any smelting process. For example, the heavy sulphuret ore is delivered to Mr. Fryer in massive blocks, as blasted from the mines, and in a few hours he is able to give a very high per cent. of the assay value in silver and gold in good, pure condition, and show the ore tailings pulverized far finer than by any known mechanical process now used.

Some shrewd ones try to show some possible motives for fraud in the matter; those having the most favorable means of judging, see no common sense, or common experience in that supposition, for Mr. Fryer's methods and dealings have not been of the character of a "fraud."

Grass Valley and Nevada say to the suggestion, "if he is a fraud, we could stand any amount of the same kind, for it pays its own way." One very reflective mind suggests "that if it was real it would come out quick and he done with it." But those who have noticed the many disadvantages under which Mr. Fryer labored on entering on this problem here as a stranger less than one year ago, are well satisfied that he has already done more than all the experimenters and scientists in this department have done for the last twenty years. They say for a young man and entirely unused to our processes and methods he has surely accomplished much in short time. The patents and preliminary experiments will soon be perfected, so that the public may have the opportunity to judge more satisfactorily as to its ultimate success. But the present verdict of those best posted as to what it is doing is that it is a success.

Product of the New Almaden Mine.

Through the courtesy of Mr. J. B. Randol, general manager, we are enabled to give the production of the New Almaden mine for the year 1875, in flasks of seventy-six and a half pounds each:

Months.	Flasks.
January.....	850
February.....	800
March.....	1,033
April.....	850
May.....	1,036
June.....	1,050
July.....	1,220
August.....	1,100
September.....	1,200
October.....	1,250
November.....	1,700
December.....	1,600

Total..... 13,648

The total product of the mine for 1874 was 9,084 flasks, making the increase this year 4,564 flasks, or nearly fifty per cent. Those who supposed, from the low production of last year, that the New Almaden had nearly given out, will be surprised to learn of the great increase in production this year.

The mine still holds its well earned reputation of being the most productive quicksilver mine in California, and, consequently, in the United States. For several years the percentage of ore worked was something marvelous. The first year the mine was worked the ore yielded 36.74 per cent. In 1874 the percentage was 2.96, and the yield the smallest experienced at the mine. The total product of the mine from July, 1850, to December, 1875, has been 612,173 flasks of quicksilver, of seventy-six and a half pounds each. At the mine many improvements in the reduction of ore, etc., have been made by the manager, J. B. Randol and the foreman, Mr. Fiedeler. As soon as it can be prepared we shall publish a table, showing the production of quicksilver at New Almaden from July, 1850, with all the details of yield of classes of ore, etc.

Academy of Sciences.

The annual meeting of the California Academy of Sciences was held on Monday evening last, Vice President Edwards in the chair. W. E. Burleigh and Mr. Louis Nonsbunmer were elected resident members. Dr. Henry Gibbons, Sr., was elected an honorary life member for long and distinguished services to the Academy. The principal business of the evening was the reading of the annual reports of officers, from which it appears that the institution is in a very flourishing condition.

The chairman observed that as the President of the Academy, Mr. Davidson, is still absent and will not return until a few weeks more have passed, the duty devolved on him of delivering the annual address. This year which has just closed had been indeed for the Academy a most eventful one—one from which it seemed to him that the Academy would take its new life, and which would mark its strongest and most vigorous advancement. The Academy is poor no longer. By the great benevolence of one man, Mr. Lick, the financial burdens of the society have been removed, and the organization could confidently look forward in the future to basking in the sunshines of prosperity. The property on Market street is now wholly in the hands of the Academy, the restriction in the former deed having been entirely removed. The rents give an income of \$3,800 at the present time, and the rapid progress of San Francisco will in a few years considerably enhance that sum. The number of members added to the list is twenty-seven, of whom two are life members. Some have resigned, and three have been lost by death. There are now 500 members, including seventy-eight life members. Many of the members are in arrears in the matter of dues, and to cure this, as well as to promote activity in the interests of the Academy, Mr. Edwards recommended that the names of all drones should be dropped from the list. The condition of the Academy on the whole is satisfactory. He was able to speak of a high scientific progress by the Academy. Dr. Kellogg, having an important commission to execute in connection with the Centennial, has been absent most of the year, and his place has been taken with great efficiency by W. G. W. Harford. The collection of fishes has been classified by W. R. Lockwood; the minerals arranged and labelled by C. D. Gibbs; the osteological collection and the Academy's valuable series of crania arranged by Dr. Stont; and Mr. Gruber has classified the collection of birds and promised to make such additions as will complete the series belonging to California. The donations to the museum during the year have been numerous and valuable. The museum now contains a number of duplicates, and to these the Academy should give its attention, in order that by exchanging for others not in the collection of natural history, the museum may be made more complete. For instance, the duplicates in the crustacea might be exchanged for specimens found on the Atlantic seaboard and in Europe. For the proper display of the natural history specimens, more cases are needed. The library has increased considerably in the number of volumes, and it has been enriched by a most exquisite series on entomology, profusely and beautifully illustrated. The library will soon be completely catalogued. Reference was made to the principal papers read during the year. Through the public spirit of a few generous men the botany of California will receive ample attention in a work soon to be published. The gentlemen who have given their aid in this commendable undertaking are Leland Stanford, J. C. Flood, Lloyd Tevis, R. B. Woodward, H. Pierce, D. O. Mills, John O. Earl, Wm. Norrie and H. McLaughlin. On the subject of continuing the geological survey, Mr. Edwards, while he hoped the work would be resumed, remarked that the money being given for a special purpose, it is only fair that the givers should have something to say about the carrying out of the survey, and in future some conditions as to results might accompany the grants. In carrying forward the scientific objects of the Academy, he suggested that, as in Europe, some plan should be devised of sectionizing the members according to their proclivities—some devoting themselves to geology, others to botany, others to entomology, etc., and that each section, meeting weekly, should pass on papers, and if approved have them presented at the fortnightly meetings of the Academy. The remainder of the address was prolific in suggestions on the policy which will lead the Academy on to higher scientific eminence. On the conclusion of the address Mr. Edwards was loudly applauded.

Mr. Yale, Secretary of the Board of Trustees, read the report of that body, showing the financial condition of the affairs, of which the following is a summary: Amount in Bank of California, February 20th, at the time the Board of Trustees of 1875 took charge of disbursements, \$2,900; endry deposits to date, \$1,769.78; re-transferred from the Bank of London and San Francisco to the Bank of California, \$1,293; expenditures for museum, \$558.55; salary and commissions, Curator of museum, Secretary Board of Trustees and Treasurer, \$1,021.15; rent, \$1,650; expense account, including fuel, cleaning, etc., \$142.40; advertising, \$32.80; printing, including proceedings, blanks, checks, vouchers, abstracts, receipts, postal cards, labels, etc., for museum, \$679.89; stationery and binding, \$89; freight

\$6.70; water, \$6; repairs to building, gas fixtures, etc., \$132.92. Total expenditures, \$4,369.05; balance in bank, December 31st, 1875, \$1,593.73.

The reports of the Secretary (Mr. Yale), Librarian (Mr. Fisher), and Director of museum (Dr. Kellogg), were then read. The Secretary's report stated that the average attendance at meetings during the year was 31; new members received, 27; total number of resident members, 371; and of life members, 78. There had been some 49 papers read by members during the year.

Mr. Fisher reported the library in good condition. It had all been re-arranged, catalogued according to sciences and put in good order for reference.

Dr. Kellogg reported that a great improvement was manifest in the museum, through the exertion of W. N. Lockington, C. D. Gibbs, W. G. W. Harford, Dr. Stout and F. Gruber; it had all been re-arranged, specimens identified and labeled, new alcohol added, and the whole generally overhauled and put in order. A formal vote of thanks was made to these gentlemen

Golden-Winged Wood-Pecker.

Our illustration this week shows the golden-winged wood-pecker. It is an inhabitant of all parts of the United States and of Canada. At all times animated and happy, these birds are peculiarly so at the love-making season of early spring, when their voices may be heard in the utterance of joyous sounds, and when the coy female is pursued by several males until she has indicated her preference, which produces no strife, as the rejected at once fly off elsewhere to woo. The song of the male, at this season, is not unlike a jovial laugh, nor by any means unmusical. As soon as mated, each pair immediately proceeds to excavate the trunk of a tree, and fashion a place for themselves and their young. The hole is at first made horizontal, and then downward about six or eight inches. They caress each other on the branches, climb about and around the tree with apparent delight, rattle with their bills against the tops of the dead hrnsches, chase away the

GOLDEN-WINGED WOODPECKER.

in recommendation of the Board of Trustees. A resolution of thanks was also passed to Gen. D. D. Colton, for his generous gift of books of reference in entomology. The chairman was requested to appoint a committee of five to give effect to his suggestions of sectionizing the Academy.

The annual election, which was held during the day, was quite an exciting one. There were two tickets in the field, Regular and Independent. The Regular ticket won the day with one exception, that of Henry C. Hyde, second vice-president, who was elected from the Independent ticket. The following were declared duly elected officers for the ensuing year.

President, George Davidson; first vice-president, Henry Edwards; second vice-president, Henry C. Hyde; corresponding secretary, Theodore A. Blake; recording secretary, Charles G. Yale (of the MINING AND SCIENTIFIC PRESS); treasurer, Edward F. Hall, Jr.; librarian, Wm. J. Fisher; director of museum, W. G. W. Harford; trustees, D. D. Colton, J. F. Miller, Thomas P. Madden, R. E. C. Stearns, Wm. Ashburner, George E. Gray and Ralph C. Harrison.

A VEIN of gulens twenty-seven feet thick has recently been struck in the Yosemite mine, Bingham canon, Utah.

red-heads, and feed abundantly upon ants, beetle and larvae. Before two weeks have passed, from four to six semi-transparent eggs are laid. Two broods are thus produced in each season.

This species is scarcely less happy when domesticated in confinement than when enjoying the utmost freedom, feeding well, and finding amusement in everything, but especially in the destruction of wooden furniture, for which it has great capabilities.

The flight of this bird is strong and prolonged, being performed in a straighter manner than that of any other wood-pecker, though it propels itself by numerous beats of the wings, with short intervals of sailing in an almost horizontal direction. The migrations, which are but partial, are performed in the night, and are only known by the note it utters and the whistlings of its wings. The movements of one of them upon the side of a tree, or upon the ground, are very quick, though it only alights upon the earth to pick up a beetle, caterpillar, or other insect, or perhaps a grain of corn. Apples, cherries, grapes, peiraimons, raspberries, dogwood berries, and even whortleberries and poke-berries afford it food at certain seasons; but the farmer's grain is often its feed despite of traps and scarecrows, though the farmer often makes his meal of it.

Mr. Audubon says: "The young of this species frequently have the whole upper part of the head tinged with red, which, at the approach of winter, disappears, when merely a circular line of that color is to be observed on the hind part, becoming of a rich vermilion tint. The hairy, downy and red-cockaded wood-peckers are subject to the same extraordinary changes, which, as far as I know, never reappear at any future period of their lives." This happens to both sexes. He further says: "This occurrence is the more worthy of notice, as it is exhibited on all species of the genus."

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

SEED SOWER AND CULTIVATOR.—Chas. F. Keller, Haldsburg, Cal. This invention is an improvement in cultivators and seed sowers, and consists in a novel method of making the cultivator adjustable, so as to be used simply as a cultivator, or so that it will form the drills and cover the seed when used with the seed sowing mechanism. It also consists in a novel mechanism for dropping the seed, by the use of which the inventor is enabled to regulate the spaces minutely and sow or plant at any distance apart.

SPITTOON MAT AND CARPET PROTECTOR.—John Lse, S. F., Cal. This is a mat for spittoons, so constructed that it will catch and retain anything that misses the spittoon, and prevent it from running upon the carpet. The mats are made circular, of metal, paper mache, or other suitable material. The mat is made larger than the spittoon, leaving a wide margin around it. This margin or rim is stamped or otherwise formed into cells or depressions, so that any spittle that misses the spittoon will be caught in the marginal cavities, and be prevented from running off on the carpet or floor. The rim of the mat is ornamented in any desired manner to correspond with the carpet upon which it is placed. The mat can be removed and cleansed when desired.

ROTARY PRESSURE BLOWER.—W. L. Palmer and I. W. Knox, S. F., Cal. This invention relates to certain improvements in pressure blowers, and it consists in constructing the arms of the two pistons upon certain peculiar curves, by which a close fit between the circumferences of the two drivers is maintained, and thus utilize the machine upon blast furnaces and in other places where positive force is necessary to produce a sufficient blast. In the construction of so called pressure blowers, as heretofore made, the arcs of circles have been used to form the shapes of the drivers or pistons, and by varying the length of the chords, while the same arcs are used for the sides and ends, an attempt has been made to obtain a perfect fit between the two pistons at all points of their revolution. This has not been effected, however, and as a consequence this class of blowers have been failure whenever there has been any back pressure developed. In order to overcome these difficulties, these inventors construct the heads and sides of their pistons upon epicycloidal curves in the manner patented. They say it is found that when a blower of this construction is set up, every point of the periphery of the two pistons will exactly meet as they rotate and the fit will be so perfect that the machine becomes a pressure blower, capable of working against a resistance without stop or waste.

PRINTING PHOTOGRAPHS.—Benjamin Swesey, S. F. This is an improvement in printing photographs and the ornamental background which it may be desired to introduce into any scene or picture, so that photographic prints may be obtained with scenic or artistic accessories, from plain negatives without the necessity of double printing. In the ordinary method of double printing photographic pictures, it has been customary to print a picture and carefully cut out an outline of the figure. The remainder of the picture or plain background is then secured upon the negative so that any number of figures, alone, can be printed, the background being stopped out. The figure is then in turn carefully secured upon the negative of the ornamental background which it is intended to use, so as to stop out or cover the figure which is already printed upon the sensitive paper, and thus the figure and any desired background are printed by two operations. It has been discovered that on the ordinary printing of a negative figure upon sensitive paper without stopping out the original background, an ornamental background having the figure stopped out and properly obscured or shaded can be printed upon the plain background already printed. This process has been patented, but it also takes two operations for printing. Mr. Swesey's improvement consists in making the background negative in such a manner that he is enabled to print both picture and ornamental background in one operation, and it consists in the use of a negative background upon any transparent or translucent substance, as gelatin, collodion or paper, either photographed or produced from steel or copper plates, lithographs or wood cuts by the use of printers' ink, so that this background negative can be placed upon the original negative, and the two can thus be placed on the printing frame and be printed at one operation.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the pincers are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the pincers are grasped by both hands, and the grooves cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the pincers is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CARLES R. DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. eowbp

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time. It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in 4, 1/2, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

FACTORY: SAN FRANCISCO, CAL.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing. It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washful of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterwards. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Suprs. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES and DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES and DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES and DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES and DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

SANBORN & BYRNES.

OF INTEREST TO MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practiced in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line, for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

Thursday Noon our last forms go to press. Communications should be received a week in advance and advertisements as early in the week as possible.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

Buffalo Excelsior Pony Planer & Matcher.

Patented March 20, 1875.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines.

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc. Send for Circulars.

HARRISON'S

LIGHT VERTICAL BURR MILLS

BARRE & BACON, MILLERS AND LOUISIANA DEALERS, SOUTH VERMONT, VT., write July 15th:

"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,000 lbs., or 434 bushels. To do this we have to run at speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the result."

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

GRASSHOPPER M. Co.—January 4th. Location: Mojito Gulch, Calaveras county, California. Capital stock, \$3,000,000. Directors—F. W. Robinson, J. M. Curry, Vernon Seaman, George H. Dell and T. B. Beach.

EAST CALIFORNIA S. M. Co.—January 5th. Location: Nevada. Directors—Wm. F. Anderson, R. E. Brewster, E. Green, John Rosenfeld and M. M. Wheeler. Capital stock, \$10,000,000.

OSBERT M. Co.—January 5th. Location: Eagle valley mining district, Ormsby county, Nevada. Directors—O. Coats, S. E. Thornton, Thos. Wallace, R. B. Noyes and P. B. Moore. Capital stock, \$10,000,000.

THE assay office and bullion department of the Consolidated Virginia mine will have a capacity for assay and melting bullion to the amount of \$5,000,000 per month. Like every other part of the works, they are to be greatly improved. A condensing flue of brickwork 2½x5 ft will be run the entire length of the building, 100 feet and return, which will give a flue 200 ft in length before commencing to ascend the chimney, which will be 88 ft in height. The bottom of this flue will be sheathed with iron to assist in saving the gold and silver drawn off in the fumes from the furnace.

A TUNNEL, which W. M. Simpson is running on the West Weaver, Trinity county, caved in last week, and the neighbors somehow got the impression that the owner was reposing somewhere in the howls of the hill. After a hundred or more had been engaged half a day in throwing dirt like a lot of hangers, Simpson appeared over the slope and relieved their solicitude.

In the Justice mine ore extraction and development goes steadily ahead at the 400 and 600-ft levels, the daily yield being about 30 tons per day, which is being reduced at the Spring Valley mill.

A VERY large force of workmen are still engaged in repairing the Felton railroad. Rapid progress is being made, and the road will be ready for the transaction of business in a few days.

A GENTLEMAN who has had experience in the oil regions of Pennsylvania has recently purchased 200 acres of oil land at San Fernando, and ordered extensive machinery from the East.

It is stated that the Spring Valley mining company, at Cherokee, Butte county, have discharged their white laborers and substituted Chinamen.

THE tunnel through Town Talk hill, between Grass Valley and Nevada City, on the Colfax and Nevada narrow gauge railroad, is completed.

THE Humboldt Register says that old Humboldt City will again become a busy burg after having been deserted for years.

THE amount of bullion shipped from Palisade by Wells, Fargo & Co., the present year, is 22,424,146 pounds.

THE railroad sheds over the Sierra are in good condition, and no fear of a blockade this winter.

A GREAT deposit of copper ore has been found on Woodchuck creek, Missoula county, Montana.

THE Consolidated Virginia mine is again producing at the rate of \$1,800,000 per month.

It is suicide in the third degree, if not worse, to suffer a cough and cold to culminate in consumption, when a single bottle of HALE'S ROSEY OF HONORUM AND TAR, taken in time, would effect a perfect and permanent cure.
Pike's Toothache Drops cure in one minute.

Something of Interest to the Old Folks, and to the Boys and Girls.

THE BOSTON JOURNAL, in a recent issue, says: "Picture to yourself what a magazine for children ought to be—how bright and winning in contents, how pure and stimulating in teaching, how resplendent with pictures, and then turn over the pages of ST. NICHOLAS, and you will find your ideal realized."

THE CHICAGO INTER-OCEAN says: "ST. NICHOLAS is an institution of which Young and Old America are as proud as England is of PUNCH. A house without ST. NICHOLAS," continues the writer, "does not deserve to own any boys and girls; no dog should wag its little tail while pressing its nose through the area railings; emphatically, we would observe that should the sun descend to shine upon that house, his solar majesty would make a big mistake."

THE FIRST VOLUME of ST. NICHOLAS was a surprise even to the public that had heartily welcomed it, number by number. Newspaper critics expressed enthusiastic approval; children and parents were alike delighted, and congratulatory letters from distinguished men and women poured in upon the publishers and editor. Charles Dudley Warner wrote: "I do not see how it can be made any better, and if children don't like it, it is time to change the kind of children in this country." Whittier, our great poet, wrote: "It is little to say of this magazine that it is the best child's periodical in the world;" and words of hearty commendation came across the ocean from such earnest workers and popular favorites of the young as Geo. MacDonald, Christina Rossetti, and Canon Kingsley.

Beautifully bound, superbly illustrated, and filled with good things from the best writers, (including three long serial stories), the first volume of ST. NICHOLAS, complete in itself, is a finer Christmas gift for girls and boys to-day than any single book in the market, excepting

St. Nicholas for 1875,

Which, with its magnificent pictures, its two complete serials, and its innumerable shorter stories, sketches, poems, fairy tales, rhymes and jingles, bits of wisdom, its French, German and Latin stories—its fun and its puzzles, Jack-in-the-pulpit, the Letter-box, etc., etc., is even more superbly attractive.

St. Nicholas for 1874 and 1875, 4 Vols.

For the convenience of libraries, and because many

children find the two large volumes for '74 and '75 rather bulky to handle, we have had these twenty-four numbers bound in four elegant volumes, and inclosed in a neat box, under the general title of

THE ST. NICHOLAS LIBRARY.

These four volumes are sold for \$3, being only two dollars a volume—a beautiful and valuable Christmas present for an entire family of young folks.

THE NEW-YORK TRIBUNE says: "In the avalanche of immoral literature that threatens the children, some strong, vitally wholesome, and really attractive magazine is required for them, and ST. NICHOLAS has reached a higher platform, and commands for this service wider resources in art and letters, than any of its predecessors or contemporaries."

THE SUNDAY SCHOOL TIMES says: "A cleaner, purer more trustworthy periodical cannot be named. The magazine does not claim to be religious, but it is on the side of all that is true and good, from beginning to end."

The religious press all over the country heartily commends ST. NICHOLAS, and virtually echoes the opinion of the NEW-YORK CHRISTIAN UNION, that it is "A DELIGHTFUL MAGAZINE FOR ALL CHILDREN BETWEEN FIVE AND EIGHTY-SEVEN."

St. Nicholas for 1876

Promises even greater attractions than the previous volumes. A strong feature of the new volume is an AMERICAN SERIAL STORY,

"The Boy Emigrants," by Noah Brooks,

Giving the adventures of a party of boys on their long journey across the plains, with a vivid portrayal of their LIFE IN CALIFORNIA DURING THE DAYS OF THE GOLD FEVER. Mr. Brooks brings to this work, in addition to his well known literary gifts, a thorough familiarity with the features of that wild country and the people then flocking toward it. What he has to say of reality that enables the reader to follow the characters in their adventures with a positive sense of companionship. The contagion of the "gold-fever," the great difficulties and perils which beleaguered their journey across the plains and mountains, and finally the adventurous, half-civilized, and yet, in a certain rude way, poetic life in the mines of California, are all described with wonderful truthfulness and skill. Add to this the elevated tone pervading the work, and the irresistible attraction which such a narrative possesses for boys, and the value of this stirring, healthy serial becomes evident.

There is to be another and shorter serial, beginning in January and running through three numbers:

"Jon of Iceland," by Bayard Taylor.

A delightfully vivid story of an Icelandic boy's career, full of incidents which could happen in no other country, and graphically touching upon the customs, life, and general features of that strange land.

The best general reading for boys and girls is insured by a list of present and promised contributors, among whom are:

WILLIAM CULLEN BRYANT, GEORGE MACDONALD, ALD, CHRISTINA ROSSETTI, LOUISA M. ALCOCK, J. T. TROWBRIDGE, T. B. ALDRICH, ELIZABETH STUART PHELPS, ABBY MORTON DIAZ, HARRIET PRESCOTT SPOFFORD, DONALD G. MITCHELL, H. K., EDMUND C. STEDMAN, LUCY LARCOM, CHAS. DUDLEY WARNER, BRET HARTE, FRANK R. STOCKTON, ELIZABETH AKERS ALLEN, T. W. HIGGINSON, LUCRETIA P. HALE, PROF. R. A. PROCTOR, MRS. OLIPHANT and REV. EDWARD EGLESTON.

Special papers are secured or promised, viz: Astronomy for Young Folks (Prof. Proctor); Chapters on Windsor Castle and English History (Mrs. Oliphant); Talks With Girls (Mrs. A. D. T. Whitney, H. H., Louisa M. Alcott, Susan Coolidge and Mrs. Dodge); Little Housekeepers' Pages (Marion Harland, author of "Common Sense in the Household"); Also, incidents of American History, Practical Handwork for Boys and Girls, Sketches of Adventure and Travel, Fairy Tales, and Stories of Home Life. A Young Contributor's department is to be added to the well known and approved Regular Features; and, in short, the Magazine will be made as useful, lively, and entertaining as the purest and best writers and artists can make it.

SOME OF THE FINEST WORKS OF THE GREAT PAINTERS have been engraved for ST. NICHOLAS, and its illustrations for 1876 will surpass anything ever yet attempted in Juvenile literature.

\$3.00 A Year; \$4 for Bound Vol.

We will send the magazine for one year, beginning November, 1875, and either of the two volumes as above, post paid, for \$7.00; or a subscription one year and the two volumes for \$10.00. The price of the 4-volume edition is \$3.00. All newsdealers and book-sellers will receive subscriptions and supply volumes at above rates.

NOVEMBER and DECEMBER numbers FREE to all new subscribers for 1876. SCRIBNER'S MONTHLY and ST. NICHOLAS, \$7.

SAN FRANCISCO.At a Stated Term of the Circuit Court
of the United States of America of the Ninth Judicial
Circuit in and for the District of California, held
at the court room in the city and county of San Fran-
cisco, on Thursday, the 30th day of September, in the
year of our Lord one thousand eight hundred and sev-
enty-five. Present—The Honorable Lorenzo Sawyer,
Judge.Nicholas Selbert, complainant, vs. Wm. T. Garrett,
defendant—In equity.
DECREES.
This cause came in to be heard at the February
Term, A. D. 1875, of this Court and was argued by
counsel and thereupon upon consideration thereof, it
was ordered, and adjudged, as follows, viz: That
defendant, William T. Garrett, was not the first or
original inventor, or discoverer of the improvement
or discovery claimed by him, in and by those certain
reissued letters patent of the United States, number
five thousand three hundred and twenty-eight (No.
5328), for an alleged new and useful improvement in
lubricators, issued to said defendant, William T. Gar-
rett, on the 18th day of March, A. D. 1873, and is not
entitled to a patent therefor, and that said reissued
letters patent, number five thousand three hundred
and twenty-eight (No. 5328) are declared void and the
same are hereby vacated and set aside by reason of their
interference with those certain letters patent of the
United States, number one hundred and eleven thou-
sand eight hundred and eighty-one (No. 111,881) for a
new and useful improvement in lubricators, issued to
complainant, Nicholas Selbert, on the fourteenth (14th)
day of February, A. D. 1871.It was also further ordered, adjudged and decreed
that complainant do have and recover of and from de-
fendant his costs and expenses to be taxed herein.
(Signed) LORENZO SAWYER,
Circuit Judge.The above decree has reference to "Selbert's Eureka
Lubricator" for oiling the valves and cylinders of
steam engines.It has a glass gauge and condensing pipe, or reser-
voir, with a regulating feed valve, and works as fol-
lows: As the water of condensation is admitted, under
the oil, just so fast the oil passes out at the top through
a pipe into the steam pipe to oil the valves and
cylinder.Parties who infringe or purchase the infringed
lubricators, will be held strictly responsible.

Mining and Other Companies.

Cherokee Flat Blue Gravel Company—
Location of principal place of business, San Francisco,
Cal. Location of works, Cherokee Flat, Butte County,
Cal.Notice is hereby given, that at a meeting of the Board of
Directors, held on the twenty-eighth day of December,
1875, an assessment, No. 35, of five cents per share was levied
upon the capital stock of the corporation, payable im-
mediately in United States gold coin to the Secretary, at the
Office of the company, room 13, Safe Deposit Building,
No. 328 Montgomery street, San Francisco, Cal.
Any stock upon which said assessment shall remain un-
paid on the twenty-ninth day of January, 1876, will be de-
linquent, and advertised for sale at public auction; and
unless payment is made before, will be sold on Saturday,
the nineteenth day of February, 1876, to pay the delinquent
assessment, together with costs of advertising and ex-
penses of sale.

O. H. BOGART, Secretary.

Office, room 13, No. 328 Montgomery street, San Fran-
cisco, Cal.Owyhee Water and Gravel Mining Company.
Location of principal place of business, San Fran-
cisco, Cal. Location of mines, Elko County,
Nev.Notice.—There are delinquent upon the following
described stock, on account of assessment, (No. 1)
levied on the first day of November, 1875, the several

THE SCIENTIFIC PRESS—This valuable paper entered upon its thirty-first semi-annual volume on the 3d inst. For mechanics and miners, in fact for all classes of people, we know of no paper which contains more substantial reading matter than the SCIENTIFIC PRESS. It is published in San Francisco, by Dewey & Co., at \$4 per year. No person interested in mining or other scientific pursuits should be without it, as it is weekly filled with invaluable scientific literature.—[Amador Dispatch.]

LATEST IMPROVED HENDY & COCHRANE'S ORE-FEEDER, FOR QUARTZ MILLS.

It is confidently believed to be the ne plus ultra of ore-feeders. One of these machines, on exhibition at the late Mechanics' fair, received the premium over all competing feeders. One was recently set up at Schnabel's mill in Newcastle, Placer county, Cal. It very soon showed itself to be the thing wanted; all other feeders under examination were at once rejected, and three more ordered for the same mill. We refer to the following mills using the Cochrane feeders: St. Patrick, Pugh, Green, and Julian, Newcastle, Placer county. Keystone Con. M. Co., Lincoln and Oneida mill, Sutter Creek, Amador county. Tyho Con. M. Co., Nev. For description send for circular. J. HENDY, 32 Fremont Street, San Francisco, Cal., where it can be seen in operation. Also, manufacturer of Hendy's Improved Amalgamator and Concentrator and dealer in Quartz Mill Machinery and Machinists' Tools.

Tulloch's Automatic Ore Feeder.

SAN FRANCISCO, SATURDAY, JANUARY 15, 1876.

VOLUME XXXII
Number 3.

Colorado Bullion Product of 1875.

For the following information concerning the bullion product of Colorado in 1875, we are indebted to Mr. F. Fassett, of Central City, Colorado:

The complete bullion returns of the Central gold mining district (Gilpin county), are now in and show a product for 1875 of \$1,763,985.48, as against \$1,631,000 in 1874, and \$1,561,000 in 1873. Of the first named sum \$1,598,063.05 was gold, \$112,482.43 silver, \$51,000 copper, and \$2,440 lead. The stamp mills, of which between twenty and thirty were running at one

in 1876 as has never been known in her previous history.

The Boston & Colorado smelting works, at Black Hawk, produced \$1,947,000 in 1875. Of this \$1,356,000 was in silver, \$521,000 gold, and \$70,000 copper. The silver bars are 999 fins. The gold and copper are now shipped in bars instead of matte, the first one, worth \$23,800, having been shipped on Saturday. These works have just been enlarged and are now capable of treating 53 tons of ore daily, and the branch establishment at Alamosa has a capacity of 25 tons, comprising by far the largest establishment in Colorado. Their product in 1874 was \$1,638,000.

Among Colorado mines that have yielded from \$150,000 to \$300,000 each during the past

richer ore than the Gregory or Bobtail, but not so much of it. The profits are fifty per cent. of the gross product. The most profitable of the great silver mines at present are the Hukill and the Moose. Silver mining is just getting fairly under way and in a few years will show a yield ten times larger than that of the present time.

Central, Colorado, January 3d, 1876.

THE VIRGINIA COAL COMPANY'S NARROW-GAUGE RAILROAD.—The Virginia Chronicle says: "The surveys of the Virginia coal company's narrow-gauge railroad have been filed with the county recorder. The route is as follows: Leaving the divide, between this city and Gold Hill, the road bears around American Flat along the

Yellowstone Lake.

We present on this page an engraving representing Yellowstone lake, taken from Prof. Hayden's Government Reports on the geological survey of Montana, Idaho, Wyoming and Utah. Prof. Hayden, in speaking of the formation of the lake, says: The drainage of the country commenced long before the excavation of the present water courses, but it is difficult to answer the question how this great drainage was brought about, unless we account for it by a general elevation of the entire country, gradually sending this immense body of water, which must have prevailed all over the North-

YELLOWSTONE LAKE, (EAST SIDE.)

time and another, with an average of 440 stamps throughout the year, treated 100,000 tons of ore, yielding \$1,240,109.08, or an average of \$11.60 per ton. The Boston & Colorado smelting works obtained \$502,000 from Gilpin county high grade ores, of which \$357,000 was gold, \$94,000 silver, and \$51,000 copper. These works treated a much larger quantity of ore from other counties.

From the best attainable information so far received the yield of Clear Creek county for 1875 cannot be far from \$2,300,000, of Park county \$85,000, Fremont and the San Juan county \$300,000, all of these principally silver. Boulder gives over \$700,000, five-sevenths of which is silver, and Lake and Summit counties will foot up, principally in gulch or placer gold, \$300,000.

These figures which cannot be many thousands out of the way, make a grand total, with Gilpin county already received, of \$6,213,000 for 1875, as against \$5,362,000 in 1874, and \$4,050,000 in 1873. Over three-fifths of the above was silver. From the amount of capital coming into Colorado, the extensive mining enterprises on foot, and the erection of mills and preparations for mining on a large scale in all directions, the leading industry of Colorado cannot fail to make such an advance forward

year are the Gregory and Bobtail (gold,) at Central, and possibly the Gunnell; the Pelican and Dives and the Hukill (silver), near Georgetown; the Moore, in Park county and the Caribon, in Boulder county, both silver. Besides thousands of lodes worked on a small scale there are scores of mines that are paying many thousands of dollars annually, and occasionally tens of thousands. The older mines in many districts are being sunk downward rapidly.

The Ophir-Burroughs is down 918 feet. Six or seven other gold mines near Central have depths of from 600 to 740 feet, three of which are to have their lower workings extended down to depths of 900 or 1,000 feet. Machine drills are being introduced here, by which it is hoped a great saving in time and money may be effected.

The total cost of mining and milling on the Briggs part of the Gregory is \$4.50 per ton, and on another part of this lode and on the Bobtail and Leavitt, \$5 per ton. Average yield of mill ore, from \$7 to \$12 per ton; width of veins, from five to fifteen feet in each; number of men employed on the three lodes, nearly 400. Besides 170 tons of mill ore raised daily, fifteen tons or more are sent daily from these lodes to the smelting works, where an average of \$100 per ton is paid for it.

The Kansas and Burroughs are yielding much

dividing ridge between the Flat and Washoe valley, at a height of eight feet above the lowest sag in said ridge. It strikes the valley not far from the Mound house and the track of the Virginia and Truckee railroad, and reaches Carson City in thirteen and a half miles. It is expected that trains will run from this city to Carson in thirty minutes. From Carson to the mine of the company on El Dorado canon is nineteen miles. The road will pass through Mineral valley, and crossing the Carson river near McTearughan's bridge, go up through Mineral pass one and one-half miles above the coal mine. Between Carson and the mine is a natural grade where little is to be done but to put down the ties and rails. The heaviest grade on the whole road is but 138 feet, and the cost per mile will be about \$11,000."

THE Centennial mine, on the Comstock, is about to be started up actively. The superintendent is now in the city for the purpose of shipping up the hoisting machinery already ordered for the mine, and active work will be commenced immediately in the sinking of a first-class three-compartment working shaft.

MR. ROBERT M. FRYER has purchased the Glenbrook property, half way between Grass Valley and Nevada City. The new residence is near to the new reduction works.

west at least, perhaps all over the Rocky Mountain region, westward into the Pacific, and eastward into the Atlantic. As the waters slowly subsided they were separated into lakes of greater or smaller size, and then came the excavation of the grand canon, which slowly drained the great lake basin above the falls, so that now we have only the comparatively small remnant, the Yellowstone lake, shown in the illustration.

ON the North Consolidated Virginia mine during the past two and a half months the shaft has been sunk to a depth of 630 feet. Solid, comfortable hoisting works, blacksmith shop, carpenter shop, and an office for the foreman, have been erected, the total cost of the whole amounting to only \$44,109.67, showing a close and economical management that reflects great credit on the superintendent, Mr. D. H. Jackson.

THE water is entirely drained from the 2200-ft level of the Savage mine, and the drifts are being repaired and put in the best condition possible previous to commencing to cross-cut the ore vein in that portion of the mine.

SOUTH mountain, Idaho, is almost deserted, the works being all closed down. Business is entirely suspended.

CORRESPONDENCE.

Bingham Canon Mines.

MESSES. EDITORS:—Since my last communication mining matters here have assumed a much more cheerful aspect, with undoubted assurance of continuance. Every mine that has ever been productive is now being worked with better success than before in regard both to quantity and quality of ore. Many "holes in the ground," that their owners called mines in their efforts to sell them, have really been proven such on a little further development, consequent upon their failure to sell or engage capital. It seems now altogether probable that of the three thousand locations made in this district a large proportion will ultimately prove good mines, although the difference in depth at which the ore is struck in them is very great. On the eastern slope of the hills facing the valley, and some two miles from the town of Bingham, several milling ore lodes were found in the past fall, that are well defined, of good size and assaying \$35 to \$60 per ton in silver, and \$18 to \$20 in gold. In prospecting heretofore many of these veins had been opened, but as they showed no galena they were passed as worthless. One of these, the Mayflower, has been opened to a depth of 300 feet, at which point the vein is about fifteen feet thick, and has continued, from 150 feet from the surface to the bottom, of the average assay value of \$85 to the ton. The Winnebago, in the same vicinity, is of about the same character, but larger so far as developed. This class of mines will conduce more to our prosperity than those before known. Most of the ore in them is of about the hardness of chalk, yellow and brown, containing nodules of flint and fragments of quartz. The formation is the same as that containing the smelting ores. Mr. C. G. Ferguson, superintendent and an owner in the Mayflower, has placed substantial hoisting machinery thereon and is pushing ahead energetically. The only complaint now prevalent is the difficulty of transportation; the tramway running to the Bingham Canon railroad, it is said, does not keep the dumps clear of ore, and as the wagoners had drawn off on the completion of the former and engaged in other occupations, they are in something of a "pickle" at present.

A report, apparently reliable, comes to us that an extensive mining locality has been found near San George, in the southern part of the territory, the ores being of chloride and horn silver, the geological formation being sandstone. Now this will strike most of our readers as an anomaly, but it is not an impossible occurrence, nor unprecedented. At one or two points in Mexico the same has been found. In looking over the proceedings of the Association of American Geologists and Naturalists for April, 1845, I see a paper that was read by Dr. Jackson, giving an account of silver and copper mines occurring in sandstone in Nova Scotia and in the Lake Superior region; his deductions being that the fissures are filled with their mineral contents from below by injection, an old theory, but one that will account more satisfactorily than any other in most instances for the phenomena of mineral lodes. We will not yet draw comparison between Utah and California as regards mineral wealth, but will hold on to a "mental reservation" to do so at any time in the future.

WILLIAM TEAL.

Industries of Sacramento.

MESSES. EDITORS:—When I left San Francisco I promised to write you a statement of the manufacturing interests of this city and what the prospects for improvement were in the future. I hardly feel myself competent to predict the future of so large and prosperous a city as Sacramento. I believe that in all branches business is as good as it has ever been in the past, and judging from the way capitalists are taking hold and expending their capital in business pursuits, that the future is a great deal brighter than it has been for years. The time has now come for California to do its own manufacturing, and in a few years the large importation of farming implements and like goods will be a thing of the past, and will be a saving of over two million dollars per year.

At the present time Sacramento is manufacturing all cast iron goods that are needed. There are two large foundries, the Union and Mr. Gettenberger's. They have apparatus for raising large castings and all the modern improvements for casting large pieces.

Situated a few blocks from these foundries is a box factory, owned by Messrs. Cook & Gregory. Last season they found the building inadequate for their increasing business, and have commenced the work of enlarging it.

Mr. M. R. Rose's machine shop, situated on K street near Ninth, is doing a good business.

There has lately been formed the California carriage manufacturing company, who are now erecting a very large four-story building on the corner of Eighth and K streets, where they intend making all kinds of carriages and wagons.

They expect to be ready to commence work by spring. There are several other carriage and wagon manufactories, also furniture manufactories.

The railroad shops, situated in the north-west portion of the city, are doing more work at the present time than ever before, and furnishing employment for a great many men.

We have but one implement manufactory in this city, the Sacramento plow company. It was organized less than a year ago, and now ranks in the head of the class in this State. They have the latest improved and best machinery for the business, with a thoroughly skilled mechanic at the head. The right man in the right place is essential to all successful enterprises. This factory has turned out since it was fairly got under headway about two hundred plows per month, besides a great variety of harrows, cultivators, etc. The company have agents all over the State, and the Iron King gang plow, manufactured only by this company, has already become a standard plow of the Pacific coast. The company have a foundry of their own where the finest castings are made. The works are driven by a twenty-five horse-power engine and everything is as complete as possible. The profits of the business is satisfactory to the owners, and the works will be enlarged from time to time as the demand increases. Yours truly, F.

Mass Meeting in Relation to Mining Debris.

An adjourned meeting of the citizens of Sutter and Yuba counties was held on Friday afternoon, December 24th, at the City Hall in Marysville.

The meeting was called to order by Judge Craddock.

Dr. S. R. Chandler, of Yuba City, chairman of the committee to draft a bill to be submitted to the Legislature, to prevent the further destruction of the valley farming lands and the navigation of the Sacramento and Feather rivers, presented for the consideration of the meeting a bill, the main features of which were: That it should be a misdemeanor for hydraulic miners to hofond and fill with sediment from their mines the waters of the rivers. That employer and employee should be held equally guilty and responsible in a civil action for damages, and a judgment for damages when rendered should be a lien upon all the mine and the machinery and appurtenances, and should take precedence of all other liens. That the second offense should be punishable by fine or imprisonment, or both, in the discretion of the court. The doctor stated that he had submitted his draft of a bill to several legal gentlemen, who thought it sufficiently comprehensive, but that in its present form would be difficult to enforce. He maintained his position with ability, and argued that self-protection was the first law of nature. That the farmers had bought their lands of the government, settled and improved them in good faith, and were entitled to protection. That we might bankrupt ourselves building levees which were at the best but temporary protection against encroachments of the sediment. That unless something was done immediately we should see a large portion of the finest lands in the State turned into a desert, and the inhabitants, with blasted hopes and shattered fortunes, fleeing from their once happy homes.

Judge I. S. Belcher, one of the legal gentlemen of the committee, being called upon, said that since his appointment upon the committee he had not had time to fully consider the question so as to be fully satisfied in his own mind; that the matter was beset by many difficulties, both from a legal and financial standpoint; that hydraulic mining had now such approved appliances for moving earth that it was comparatively easy to send a large quantity down upon the cultivated lands, carrying destruction and desolation; that in law there was no principle better settled than that every man should so use his property as to not interfere with and injure his neighbor; that the hydraulic miner was injuring his neighbor was clear, but that the best remedy was not so clear; that he was willing to co-operate with the committee and give them all the assistance in his power.

W. H. Parks said it was high time that something was done. That the State could not afford to see so much of her best territory destroyed. That many well-to-do farmers had already been broken up by the sediment from the mines upon their farms. That the navigation of the Sacramento and Feather rivers was being ruined. That he with others well remembered when to be "a good miner was much greater than to be a good, honest farmer." But the thing was reversed now. That the State now must look to agriculture as one of her greatest and most permanent sources of prosperity and wealth. That he was not in favor of one industry being built up at the expense of the other; and that it was not just to use the farmers' fields as a dumping place for the mining sediment. That as a business proposition it would be better for the State to buy every hydraulic mine and pay every dollar it was worth than to permit the valley lands to be ruined as they soon would be; but he doubted whether that would be practicable, as there would be countless worthless claims for worthless mines. That the hydraulic miner was in a condition that we should carefully

consider. He has his money and business in his mine. He is sending his sediment on our lands, but are we ready to say he shall stop immediately? Are we ready for so radical a measure at once? For one, I dare not say it. I doubt whether any man here will say it, while we all feel that we are suffering a great hardship. The question is beset with many difficulties; but I believe there is a remedy, and I will cheerfully support any measure that offers the needed relief.

J. H. Keyess said: "I have no objections to the miners digging out all the gold they can find, but I don't want them to send the whole side of a hill down upon my ranch and bury me and all I have. And that is just what they have done and are doing. I want to be let alone. I don't know much about law nor don't want to. If it is the law that one man shall use his property so as not to injure his neighbor, I should like to see that law put in force. As far as I can learn, when you go after a miner for damages the miner says, 'I have not damaged you; how do you know that my sediment is on your land? There are others mining.'" Mr. K. thought a law should be passed making any miner that threw sediment into the river where it would come upon a farmer's land, responsible for all the damage, and the putting of sediment into the river evidence of such damage.

Dr. Wilkins agreed with the other speakers in that it was a very great evil, and should engage the serious consideration of all the people, and hoped that some relief may be found.

J. L. Wilbur, in suggesting a remedy, said the Legislature might find it expedient to appoint a commission to visit the localities of the mines and see if possible whether cheap and worthless lands might not be found where their washings could be conveyed to where they would at least be no injury if they did no good.

George Ohleyer was in favor of any move or compromise that would save the agriculture of the State. This being now by far the greatest interest in the State, it should receive the fostering care of all those who look upon California as the permanent home of themselves and posterity. To show what had already been destroyed, he submitted the following figures:

Twenty-four sections of land destroyed on the Yuba river—15,360 acres—valued at \$200 per acre.....	\$3,072,000
Personal property and improvements.....	5,000,000
Loss and depreciation of property in Marysville.....	2,000,000
Destruction on Feather river.....	500,000
Eighteen sections on Bear river—11,520 acres—valued at \$100 per acre.....	1,152,000
Destruction in Yuba county.....	9,724,000
Assessed value of all property in Yuba county for 1875.....	5,025,720
Assessed value of all mining property in Yuba county in 1875.....	298,600
Destruction of property in Sutter county—eighteen sections of land on Bear river—11,520 acres, valued at \$100 per acre.....	1,152,000
Personal property and improvements.....	1,000,000
Destruction in southern portions of the county, Coon creek and Auburn ravine.....	500,000
On Feather river on both sides.....	500,000
Total in Sutter county.....	\$3,152,000

The speaker estimated the total amount already spent by the building of levees to protect what is not yet wholly destroyed, at \$1,000,000. And these works, he claimed, were as yet protecting \$20,000,000 worth of property. But the filling up of rivers is gaining on our ability to levee it out, making it perfectly plain that all must soon go together. For these reasons he held that should no remedy occur short of stopping the mines, that mining should stop. Three hundred thousand dollars of mining property should not be allowed to menace and destroy property assessed at \$10,000,000, besides destroying our rivers and harbors.

On motion it was ordered that W. H. Parks, Judge Crane and Judge Filkin be added to the committee heretofore appointed to draft a bill to be presented to the Legislature, making it unlawful to flow mining debris into Bear river, Yuba river or Feather river, or their tributaries, and making any and all hydraulic mining companies so flowing debris in said streams answerable in proportion to the amount so thrown into said streams for the damage caused thereby. Also, to ask the Legislature to investigate by appropriate means this subject in order that some plan may be adopted by which the destruction occasioned by hydraulic mining on said streams may cease. And to ask the Federal Government for appropriations to keep open for commerce the navigable streams of the State rendered unnavigable by hydraulic mining.

On motion, the meeting adjourned till Saturday, January 8th, at twelve o'clock, to hear the report of the committee and take action thereon.

J. H. CHADDOCK, Chairman.

GEORGE OHLEYER, Secretary.

TUSCARORA DISTRICT.—Tom Rule recently arrived from this district and reports that everything is looking favorable, but they have been obliged to suspend operations for a while in consequence of bad weather, snow and the difficulty of getting supplies to the camp. Elko is the shipping point for this camp, but the roads, especially over the Summit, is so very bad and impassable in winter that it is impossible to get supplies in there during cold weather. It is now in such a bad condition that it is utterly impossible for the stage or other teams to pass over the route, and if some other road is not laid out all work in that district will have to be abandoned for the winter.—Humboldt Register.

Prospects of Coso District.

The Coso Mining News says: About one year has elapsed since the mines of this district were discovered, but it is only within a very few months that any legitimate attempts have been made to open them up and make them productive, and even the few enterprises inaugurated for that purpose can yet be counted upon the fingers of one hand. These few operations are even yet in their infancy and we are consequently far from occupying a self-sustaining position, but our prospects are brilliantly promising in the extreme and in a few weeks more will be demonstrated our ability to return large profits in any legitimate mining enterprises properly conducted and honestly managed. It takes time to inaugurate mining enterprises even when capital is idle and obtainable; and when the reverse is the case, as has been during the time since our resources have become known, it is extremely difficult to place mines upon the market and secure funds to work them. That we have already done as much as we have is a matter of surprise to those familiar with the difficulties to encounter and should be a subject of congratulation to all who have cast their lot in a section of such mighty resources as this contains. There has not yet been one legitimate undertaking attempted but what is more promising to-day than when commenced; this is conceded by every one who is well informed, and that such is the case is a fact not paralleled in the history of silver mining elsewhere. This assertion may appear almost incredible to some, but we speak whereof we know from a personal experience in the silver mines of this coast during a period of twelve years past in nearly every locality where the mines have obtained any prominence. That ours should be the exceptionally favored place is really a wonder and is accounted for upon the simple fact of our mineral deposits being of grand dimensions, far beyond the average richness and practically inexhaustible. With such a foundation upon which to base our wealth and future prosperity we can contentedly await the introduction of more capital that is even now headed this way and while, during the immediate present, resuming the benefits of more prosperous times than any new mining locality ever before had to boast of, we can confidently prepare for substantial and long continued prosperity to attend us in the future. With facts upon which to base such brilliant and satisfactory predictions none should hesitate to forward improvements and lay the foundation for a competence so easily attainable. No mining locations should be left unworked; though circumstances may be such as to limit the endeavor and cause the results to look meagre, all should receive attention, for herein consists our only source of wealth, and we must not allow the opportunities to pass while they are within our grasp. We should recollect that the era of new discovery in the United States is rapidly passing away and that very soon, perhaps during the lives of our children, the history of the prospector will have become a thing of the past and the wonderful opportunities of leaping from poverty to affluence by a single stroke of the pick will be foundation matter for future romances rivaling the wonders of Aladdin's lamp. We are living in an age of marvellous change, in which wonders multiply so rapidly that the senses are bewildered and when we carefully review the causes which lead to this

"Strange Mysterious change,"

We find our own locality surrounded with advantages that properly fostered will prove us the central figure of this extraordinary age. Therefore it behooves us to nourish the opportunities now within our grasp, for such rare advantages as we enjoy will perhaps with the present century pass away; the silver girdled mountains will have become the property of wealthy corporations, and the miner of to-day with chances of becoming a representative magnate among the money kings, will find himself circumscribed to the sphere of the stereotyped laborer with nothing to beneath his children but the hard knocks and wrinkled brow of care that embittered his life and prematurely hurried him under the sod.

NEWSPAPER AND SCHOOL EDUCATOR.—The newspaper is, without doubt, a powerful instrument for good or ill, according to the kind of newspaper meant, but it is no part of its mission to supplant the school. It is the business of the daily journal to print the news, to comment upon the occurrences of the day, and to advocate that which its conductors believe to be the right in all matters of public and general concern. The business of the school lies in a totally different plane. It is its province to train the faculties of boys and girls into ready and accurate modes of action, and, so far as mere information is concerned, to furnish them with a certain technical, elemental, basilar species of knowledge upon which their disciplined faculties may build as upon a foundation wall. The information which the school furnishes, the newspaper does not; that which the newspaper gives, the school cannot and ought not; and hence, even in this matter of giving information, the only one in which there is the least resemblance between the respective functions of the school and the journal, it is resemblance only, and not identity.—Evening Post.

MECHANICAL PROGRESS

Iron in Architecture.

When iron fronts were first introduced it was strenuously asserted by some that expansion and contraction would dislocate the joints and render a building unsafe. An examination of one of the numerous cast iron structures which, for a number of years, have been exposed to every change of atmospheric temperature without, and to the heat of steam boilers, etc., within, will show everything unchanged. Events have also proven in the cases of burning of storehouses, filled with combustible goods, that cast iron fronts are absolutely fire proof, and will neither warp nor crack, nor fall down, unless the entire building falls, pulling the front with it. Only let it be remembered that, in addition to a high and intense heat, the use of a blast is required to reduce cast iron to a molten state, and the ability of iron fronts to stand heat will be readily understood. Iron fronts have stood erect in cases where the side brick walls were entirely thrown down and demolished by the elements.

A front of iron is usually laid down and fitted together complete in the manufactory previous to erection at the building. It can be transported to any distance to the place of erection and put together with wonderful rapidity, and at all seasons of the year. It takes up less space than any other material, and so enlarges the interior of the building. When it becomes desirable to tear down the building itself, to make way for other improvements, the iron front may be taken to pieces, without injury to any of its parts, and be re-erected elsewhere with the same perfection as at first. Instead of destruction there need be a removal only.

Iron has in its favor unequalled advantages of ornament, strength, lightness of structure, facility of erection, durability, economy, incombustibility and ready renovation.

Mach has been said against iron from misconception. It is exceedingly difficult in the minds of most writers and talkers who use sweeping denunciations and citations against iron, to separate wrought iron and cast iron in their respective endurances against weather. Wrought iron rapidly oxidizes when exposed to the atmosphere, and goes to decay. Cast iron, on the contrary, slowly oxidizes in damp situations; rust does not scale from it, and the oxidation, when formed, is of a much less dangerous kind than on wrought iron. A coating of paint will counteract whatever tendency cast iron has to rust when exposed.

Whatever has been done in iron which deserves censure from critics, can be remedied. Let it not be forgotten that the material is not at fault but the workmanship. Iron can be made to imitate anything perfectly. Men who have said the most against iron have been they who knew the least about it. Arguments have been made that iron is a sham, but a stone building is a greater sham, because it leads one to believe that it is all stone, when in fact it is usually nothing but a veneer set up against a brick wall.

When the public become thoroughly acquainted with the advantages iron possesses as a building material, it is confidently predicted that for superior buildings of all kinds, it will receive a general preference to granite, marble, sandstone or brick.—*Condensed from Iron Age.*

Painting Iron Fronts.

A great deal has been written about the color to paint iron work. Iron being a material which requires a coating of lead and oil, it is proper to give it any color that good taste may suggest. The color will often be regulated by the color and hue of adjoining buildings or other surroundings. Because marble is white or sandstone brown, the painting of iron work in these colors must not be prohibited. What is to be condemned is the graining of iron in imitation of marble and sanding in imitation of stone. Tints and colors and gilding produce rich and sparkling effects, but great care and exceeding good taste must be exercised or failure will be the result. The best pigments must be used, or the colors, exposed to the air and sun, will fade rapidly—and the best do fade—and leave the front shabby. Wherever practicable, iron work should be painted inside and out, without delay. Particular care in this respect should be given to all parts put together in pieces, as cornices, trusses, etc. These should have their joints well painted before being bolted or riveted together. Painting on the inside, however, applies only to the shell parts. Columns cannot be painted on the inside, nor do they need it. Columns stand over column with an intervening plate; the very construction makes of the inside of a column an almost air-tight chamber, where the air is always dry and always of one temperature. No oxidation takes place under these conditions, and so no paint is necessary. The inside of a column is covered with a coating of foundry sand, which clings to it for ages. On the shell work, when the paint has fairly reached every crevice, these parts, too, become air-tight, and paint only becomes requisite on the outside, and to brighten up the color. In applying ornaments, such as leaves of capitals, etc., not only should the ornaments themselves be first thoroughly painted, but the screws which fasten the ornament to the main work should be dipped in paint as well. After drilling a hole in iron, the burr around the hole

should always be filed away, so that no streaks of rust from rain water down the face of the building will tell of carelessness in this respect. A lack of care in such little matters often causes the greatest annoyance, and has been the obnoxious reason why iron fronts have had to be painted more often during the ensuing few years of their erection than afterward. Some fronts in a dark color have only been painted for intervals of five years during the past twenty years, and previous to that did not average more than once in two years. For the first coating of iron nothing is superior to oxide of iron mixed with oil, or what is known as metallic paint.—*Iron Age.*

Sixty vs. Thirty-Foot Rails.

The statement made by us some weeks since that the Edgar Thomson steel works had not only rolled a specimen sixty-foot rail but had filled an order for some of the same length, has called out considerable discussion as to their superiority over the ordinary thirty-foot rail, which has generally been in favor of the sixty-foot. In the first place they of course cost no more per pound than the thirty-foot, and even less, while two crop ends are saved. This is an item of no small moment. How to use crop ends economically is one of the serious problems at Bessemer works. Two thirty-foot rails give four crops, and a sixty-foot but two, which at once takes out of the question fifty per cent. of the difficulty. With a view to this cheapening of production by reducing waste these works were designed to make sixty-foot rails.

The saving in their use by railroads is not so evident, but it would doubtless be found more economical to use the longer rail. The cost of laying them will be less and the wear and tear of rolling stock as well as the rails themselves will be much lessened. A larger part of this wear and tear is due to the "hammering" caused by the shock in passing from one rail to another, and on a track with sixty-foot rails the number of joints will be lessened one-half.

Some of the sixty-foot rails ordered have been for laying on bridges, on the supposition that reducing the number of joints will reduce the strain on the parts of the bridge.

What the effect of expansion upon a track laid with these longer rails will be is doubtful. Of course with only half as many joints the distance between the rails allowed for expansion and contraction will have to be greater, but in arranging the track for hot and cold weather only half as many joints will have to be extended to.—*American Manufacturer.*

A New Style of Ship Building.—"Composito."

There was recently launched at Baltimore, for the United States coast survey, a "composito" vessel, that is, a vessel built partly of iron and partly of wood. It appears that this vessel was built upon recommendation of Capt. Patterson, of the coast survey, whose views on the subject are of interest in addition to our knowledge of the important questions affecting the ship building trade. He says that experience has shown "composito" vessels to be more economical and more durable than vessels built either entirely of iron or entirely of wood, and that this is more especially the case in our Southern waters. In the "composito" built, the frame and beams are of iron, and the planking of wood. The waters of the Southern coast are found to seriously affect iron hulls, so that after about eight years the iron fails. Five or six years ago two small "composito" vessels were built for the coast survey, in Baltimore, and they have proved very successful; one of these, the *Bibb*, withstood the terrible cyclone which recently destroyed Indianola. She was subjected to its full severity for ninety hours, but passed through it unscathed. In the period of nearly six years that they have been afloat, the repairs to these two schooners have not exceeded \$600. Subsequently another "composito" schooner of 125 tons was built, and afterward a "composito" steamer of 200 tons. Captain Patterson thinks that this class of vessels will in time be generally used, on account of their much greater durability than wooden vessels, which much more than balances the somewhat heavier first cost.

A NEW STYLE OF BRIDGE.—The recent discussions on the subject of widening London bridge, and the anxiety which prevails to provide suitable means for relieving the present congested state of the traffic crossing the Thames, has brought forth several schemes for effecting that object. Among others is a proposed new bridge, patented by Mr. F. Barnett, O. E., who, not long since, explained the plans and designs of it to a gathering consisting of gentlemen interested in the shipping and carrying trades of the port of London, engineers and others, at 104 Queen Victoria street. The bridge is constructed on girders, and double openings are placed at intervals throughout its length, into which large ships can enter through gates conducted on dock principles. The scheme is simple in its arrangement, and the chief advantages claimed for it by the inventor are that it can be constructed at a comparatively cheap cost, without having the effect of depreciating the valuable wharf property that exists on both shores below London bridge; that it will obviate great loss of time, and wear and tear of horses and vehicles, and that it permits of the passage of ships without necessitating the stoppage of vehicular or pedestrian traffic for a moment.

SCIENTIFIC PROGRESS.

The Interference of Light.

The undulatory theory of light is now universally admitted to be the true one, and by it many things may be accounted for which otherwise have no rational explanation. Among them may be mentioned the subject of the interference of rays of light. Tyndall has defined the interference of light as follows, viz:

"The action of one system of waves upon another, whereby the oscillatory motion is either augmented or diminished, is called interference. In relation to optical phenomena it is called the interference of light."

Bearing in mind that the same general laws apply to light and sound (and, to a certain extent, to water) we must at the same time distinguish between the motion of the wave and the motion of the individual particles which constitute the wave. For, while the wave motion may be propagated through long distances, the motion of the particles is confined to a small orbit. In the case of an object floating on water—while the wave rushes on the object is not carried with it, but appears to move up and down.

So it is in a wave of light, the motion carries the particle of ether up and down, and this distance which the particle moves up and down, is called the displacement or amplitude. One thing, however, must be borne in mind, i. e., that the action of a wave of light is in every direction from the source, so that the wave front is a sphere, and the illustration given above of an object on the water would only apply to one point in one part of the wave. Now, in the case of light proceeding from two different sources, it can easily be seen that the waves from one must have an effect upon those from the other.

Tyndall illustrates this by taking the case of two stones dropped into still water at the same time. Little waves will begin to radiate from each in circles; at some point the first, or outside ripple from one stone will reach the first ripple from the other. Now, it will be seen that if the crests of these two happen to meet, the tendency of both is to "push up," or, if the furrows meet, the effort of both is to "push down," and the result will be that when crest coincides with crest, or furrow with furrow, the height of the crest and the depth of the furrow will be twice that of either alone.

If, on the other hand, the two ripples happen to come together in such way that the crest of one strikes the furrow of the other, the tendency of one will be to elevate while that of the other will be to depress; and, supposing the two waves equal, the result will be that the two actions will counteract each other, and stillness will be the result.

This phenomena of motion added to motion, producing no motion, is called interference; and when these phenomena relate to light, they are called the interference of light, and by the principle of interference are explained some of the most beautiful phenomena in nature.

A Valuable Gift by Chemistry to the World.

A celebrated physician, the late Dr. Valentine Mott, used to say that iodine was the greatest gift which medicine had ever received from chemistry; and it may now be said that one of the most remarkable and important services rendered by chemical investigators to the arts and sciences is the discovery of bromine, by Balard in France, just fifty years ago. Berzelius, while describing it in his "Chemistry," mentions that no use had been found for it, but he cautiously adds the words "thus far," showing that he confidently expected that a use would ultimately be found. The discovery was fruitless for a period of fifteen years, when daguerreotype was invented; and bromine soon took an important place as one of the most valuable ingredients in the necessary materials, and now bromine compounds are indispensable to the photographer. Another fifteen years elapsed; and then physicians commenced to experiment with the new element, and they soon ascertained its great value as a remedial agent, and the salts of bromine now form a series of the most important substances in the materia medica. Lately it has been found that bromine and some of its compounds are the very best etching materials for engraving metals, surpassing all acids and other agents. But there is no reason to believe that this will close the list of the uses of this remarkable elementary substance, which is found in sufficient abundance in the waters of the sea and of many saline springs to make it comparatively cheap.

Bromine is commonly obtained from the mother liquor or bitters of salt works, which is rich in bromine compounds, the latter being retained in the liquor, as they do not crystallize out as easily as the chloride compounds, of which common salt is the principal. Pure bromine is a virulent poison. When a small piece of phosphorus is thrown on a few drops of bromine in a tall beaker glass, it is at once violently projected upward with an explosive noise, and in an ignited condition; this forms a striking lecture room experiment, illustrating the effects of very active chemical affinity.

Bromine is a very disagreeably smelling brown liquid, freezing at -8° Fah., and boiling at 150° , when it changes into a deep red vapor,

nearly six times heavier than the air. The production of bromine at present equals 245,000 pounds, of which the United States and Germany produce the greatest part, namely, 100,000 pounds each. Scotland produces 30,000 pounds, and France 10,000 pounds.—*Scientific American.*

Deep Sea Soundings.

Not so many years ago it was considered a feat in deep sea sounding to reach a mile or a mile and a half, and even then, after allowance had been made for the action of currents upon the line, the actual depth attained was a good deal matter of calculation and guess. Breakages also were continually occurring in the hauling up, from the necessary slenderness of the cord in comparison with the weight of the lead. The modern method by which the lead detaches itself at the bottom meets that as well as several other difficulties nearly as important, and the wonder is that it was not thought of sooner. Now there is scarcely any limit to the depth of soundings, except the depth of the sea, which the recent explorations of the *Challenger* go far to show to be in accordance with the theory that its greatest depth is equivalent to the height of the highest elevations above its level.

The deepest sea soundings yet effected were obtained by the *Challenger*, in the abysses off New Guinea, depths which have occasioned a sharp line of demarcation between the fauna of Asia and Australasia. The "lead" weighed four hundred pounds, and struck bottom at the tremendous depth of 4,575 fathoms, or a little over five miles. The hollow rod, by which specimens of the bottom are brought up, was full of mud, and both the thermometers that had been sent down were smashed to atoms by the enormous pressure of the superincumbent water. A previous unsuccessful attempt to reach the bottom, but in which 4,545 fathoms were sounded, showed the temperature at that depth to be $35\frac{1}{2}$ degrees Fahr.

In the attempt to ascertain the temperature at this great depth, three out of four thermometers that had been sent down were crashed by the enormous pressure of the superincumbent water, amounting to over six tons to the square inch.

Piano wire is now used instead of cord for deep sea soundings, and has done excellent service in recent submarine cable expeditions.

Pressure and Compressibility of Water.

Oerstedt of Copenhagen, who in 1819 discovered the relation between electricity and magnetism, a discovery which was the first step in the invention of the modern telegraph, was the first who practically demonstrated and measured the amount of compressibility of water and other liquids, by means of an apparatus still named after him. It consists of a small hydraulic press, of which the piston is pressed powerfully down by means of a screw, so as readily to produce pressures of 500, 1,000, and even 5,000 and more pounds per square inch. The walls, being of extremely strong glass, give opportunity to observe the instruments of measurement enclosed. Experiments with this apparatus show that water at a depth of thirty-two feet exhibits a pressure of fifteen pounds to the square inch; at 100 feet, seventy-five pounds pressure; at 1,000 feet, 750 pounds; at one-half mile, 1,200 pounds; at one mile, 2,400 pounds; at two miles, 4,800 pounds; at three miles, 7,200. The pressure at any number of miles of depth may be ascertained by multiplying 2,400, the pressure at one mile in depth, by the number of miles given. For example, 2,400 multiplied by six equals 14,400, which represents the pressure at a depth of six miles.

When water is subjected to the pressure of 14,400 pounds (six tons,) to the square inch, (corresponding to six miles ocean depth) a bulk of 1,000 cubic inches is only reduced to 957 cubic inches, specific gravity 1.044, water at the surface being 1.000.

DO GREAT FIRES PRODUCE GALES AND WHIRLS?—There has been much said in the newspapers of the high wind which prevailed at the time of the Virginia City fire, and we have yet to learn whether the wind was blowing when the fire began or whether it was occasioned by the fire. It is generally supposed that the great Chicago fire broke out during the prevalence of a gale of wind, but such is not the fact. On Saturday preceding the fire there was a terrific gale blowing from the west, but it had spent its force before Sunday morning, and the afternoon and evening of that day a perfect calm prevailed. And it is a remarkable fact that, during the early hours of Monday morning, there was but little wind ten blocks west of the great path of fire through which a hurricane seemed to be sweeping. This statement can be verified by scores of witnesses who lived west of the river, and we have never had an explanation of the phenomenon. The fire itself created the wind which fed and fanned it, and drove it through the heart of the city with such appalling speed.

However much we may endeavor to comfort ourselves with the thought that a great fire in New York would not be exposed to such winds as came from off lake and prairie, it may nevertheless be true that a vacuum caused by large currents of ascending flames would, even here, produce just such another tornado as prevailed during the Chicago fire, before which New York's proud structures would turn to ashes. Indeed we see no reason why the lesson of Chicago may not yet be repeated in New York, and indeed there is none.—*American Artisan.*

The Mining Share Market.

The mining share market during the past week has manifested no very marked peculiarities, prices having fluctuated very little. No important rise is expected as yet, and the general opinion is that prices will be lower before they are higher; of this, however, no one can make any reliable predictions. The Stock Exchanges held their annual elections this week, the result of which will be found in another column. Concerning "investigations" of mining companies very little has been accomplished as yet. The Gila investigation amounted to little—the old board of trustees having been re-elected. The Woodville company, at a meeting held on the 6th inst., appointed J. J. Green, Charles E. Harris, W. C. Nesl, W. S. Barrett and J. V. Sims, stockholders of the company, a committee of five to examine in behalf of the stockholders into its affairs, and they were authorized to receive and examine all books, vouchers and accounts of the company and the affairs thereof, and also to examine into the conduct and management of its present and past officers, and report the same to an adjourned meeting of the stockholders, to be held on Wednesday. The meeting, which was to have been held on Wednesday, was postponed at the request of the company.

OTHER COMPANIES—NOT ON THE LISTS OF THE BOARDS.

mittee appointed at the last meeting to investigate the affairs of the company, and who are not yet ready to report. Due notice will be given when the meeting will be held.

Stockholders of Globe Consolidated are notified that on the 3d of February the question of increasing the capital stock of the company from \$4,000,000 to \$10,000,000 in \$100 shares, will be submitted to them for ratification or rejection. South Comstock stock has been increased from \$3,800,000 to \$10,000,000.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

The directors of the South Mountain Consolidated mining company have called a meeting of stockholders for the 26th of this month for the purpose of considering the condition of the affairs of said company, and determining upon the propriety of winding up its affairs and making application to the U. S. district court to have the company adjudged bankrupt; also that such proceeding be had therein as provided by the laws of the United States respecting bankruptcy.

Consolidated Virginia has declared its usual monthly dividend of \$10 per share, aggregating \$1,080,000.

Crown Point has levied an assessment of \$1.

The Northern Belle mining company, has declared its eighth consecutive dividend of one dollar per share, aggregating \$50,000, payable on the 15th inst. The hullion product of the Northern Belle mine for December was \$103,000, of which \$24,000 was produced during the last week of the month from 300 tons of ore.

Fire and water have both become elements of mischief, and it will be a fortunate circumstance indeed if the property comes out of the ordeal without serious loss. The people of Sinter Creek feel the effects of the stoppage of work upon the mine, but bravely hope for the best.

KENNEDY MINE.—Work on this mine has been totally suspended. The pumping operations ceased last week, the stock of wood being exhausted, and the roads being in too bad a condition to admit of hauling. We understand it is the determination to suspend mining for

The Ophir mining company has constructed a novel railway to transport timber and lumber from the Virginia and Truckee railroad to their carpenter shop, being laid with rails two inches wide, and with a decent of one foot in thirty. These rails are greased, and the timber placed crosswise upon them travels rapidly to its destination.

A PEAT fuel company has been organized at San Jose with a capital of \$1,500,000, to operate in the peat beds in the San Joaquin valley tule lands.

company, of Cherokee, were employing Chinamen and dispensing with white labor, and at the same time expressed the hope that the report was incorrect. We are glad to know that the report was incorrect, and that the Cherokee will not employ Chinese to the exclusion of white labor. While other companies of importance in the State have employed "Chinese cheap labor" to work their mines as a means of increasing their dividends, the Cherokee company have not employed them to the exclusion of white labor, and we are assured that they do not intend doing so. The report probably grew out of the fact that this company had allowed a gang of Chinamen to work on bottom cement, where it did not pay white labor. They first leased the ground to white laborers at one-half the product. They realized \$1.70 per day to the man for the month, and then gave it up. It was then given to Chinamen on the same terms, who worked it for awhile, and have since worked on the same class of ground another gang of Chinamen at \$1.25 per day. This is entirely independent of their regular force of miners at work in their claim, and is ground that white laborers do not care to work. The company is employing about one-third more white laborers at the present time than at any period heretofore. They have recently let several tunnel contracts, which were prosecuted with Chinese labor; but the company had nothing to do with the matter after letting the contract. We are aware that the Spring Valley company could operate their claim much cheaper by the employment of Chinese labor than they have heretofore and now do by white labor, and we are glad to be able to record the fact that the company remains true to its principles, and will continue to employ white laborers so long as their mines confine to yield and laborers desire employment. Their liberality in this respect is worthy of imitation by other companies.

CALAVERAS.

WEST POINT DISTRICT.—Calaveras Chronicle, Jan. 8: M. D. Baker, superintendent of the Chesno, accidentally hurt his left hand badly while adjusting the hoisting machinery. The lower south level is still running in bonanza, showing in face forty inches of fair ore, which contains principally sulphurets of iron; also free gold. The south pay chute in this level is now over 40 feet in length. Main shaft of Mina Rica 293 feet deep and sinking. Fissure in bottom of shaft is five feet; handsome walls, especially the foot wall. Ore in bottom shows gold freely. A detached, very rich streak is making on the hanging wall. All the dikes which have been met with in the workings above have now disappeared (generally, dikes cut lodes at right angles in this district). The lower levels are being extended rapidly, as the veinstone and country rock are easier mined than above. A recent partial clean-up at the mill indicates excellent results. Amalgam retorted \$7 per ounce.

GLENCOE DISTRICT.—The Grasshopper is under headway. A large number of the principal mines are in need of building and mine materials which cannot be had, excepting in small quantities, on account of bottomless roads. The reopening of the Wolverine has been postponed until the beginning of fair weather.

LATER.—Ore worth \$150 per ton was struck in the south level of the Chesno this (Wednesday) evening. The rich ore is fully two feet thick and swelling. Full width of ore body 40 inches.

LOS ANGELES.

MINING INTERESTS.—Los Angeles Herald, Jan. 2: The mining interest has not hitherto been of much consequence, though in this county gold was first discovered in 1833. In San Gabriel canon, 18 miles from Los Angeles, is a silver bearing lode, owned by Dr. Winston, called the Zapatin mine, which promises to be very valuable, and copper, quicksilver and tin have been discovered in paying quantities in several localities. Oil has been struck in several places, and coal and marble have been discovered of good quality, though not in great abundance.

NEVADA.

PROSPECT.—Grass Valley Union, Jan. 8: The Prospect mining company is one of our local arrangements. The stockholders are working miners mostly, with a few merchants and business men coming in now and then. The trustees levy small assessments from time to time, and the money thereby raised is used for prospecting some ledge in this district. The affairs of the company are managed in the most economical way. Of late the Prospect company's workers have been prospecting the Perseverance ledge, which is located between Allison ranch and Forest springs. Last Thursday they took up some of that Perseverance ledge. The ledge is fully three feet thick and shows well in free gold and good sulphurets. The rock by mill process, according to the opinion of good judges, will yield from \$50 to \$60 to the ton. We are glad that the brave Prospect company have something good in sight. The showing is indeed most excellent. The Allison Ranch Franklin mine will soon begin work. The claims of the company are north of and adjoining the celebrated old Allison Ranch mine. A company has been organized and incorporated, with headquarters at San Francisco, and ample funds have been secured for the purpose of developing the mine. In a short time hoisting and pumping machinery will be on the ground and set up. The reducing machinery will probably not be put up until next summer, when the Fryer process can be used.

We are promised some items of interest in the history of the Allison Ranch Franklin.

PLACER.

MINING ITEMS.—Dutch Flat Forum, Jan. 6: The rain which set in on the 23d of last month, and still continues, has caused the contentment of our miners to brighten up with a gleam of indescribable satisfaction.

The storms which we had the latter part of November and early part of December were all rain and did not deposit any snow on the mountains. The present storm, however, has deposited quite a large body, so that we have now the assurance of a good water season.

The various mines in this district are being worked with vigor. The owners of these which were ready at the commencement of the November rains consider that they have at least one month's start in advance of an average season.

The Yankee claim was cleaned up a few days ago with very satisfactory results. This claim has thus far this season been washing days only; it will hereafter be run days and nights. The powder drifts heretofore mentioned were completed, and yesterday the blast, consisting of three hundred and fifteen kegs of powder, was exploded, doing splendid execution, loosening an immense amount of gravel, sufficient, it is supposed, to keep the 1,200 inches of water forced through the two immense giants at work for at least twenty days and nights.

The Central, Jehosphat, Pacific, Comet, Lekamp, Elmore Hill, Hoskin, Gold Run, North Star, Cedar, and Judd claims are all washing.

YANKEE TUNNEL.—The bed rock tunnel under the Yankee claim has reached a point opposite the Badger shaft, and the drillers have gone back fifty feet and started a branch leading to the bottom of the shaft, through which the Badger claim will soon commence washing.

This Badger claim above referred to is supplied with a hundred foot water power derrick, with an eighty-six foot boom, and everything necessary for advantageous working. The pipe is in position, and as soon as the connections with the shaft are made, the sluices will be placed in the tunnel, when this claim will be ready to step forward as one of our gold producers.

The tunnels of the Buckeye, Franklin, and Boston claims are completed, and sluices are being placed therein. All three of these claims will soon be washing and be productive, much to the satisfaction of the owners, no doubt, as heretofore the amount paid out in running these tunnels has been quite a drain on the aforesaid companies.

THE ORATEA MINE.—Placer Herald, Jan. 6: News from the Oratea mine continues very encouraging. The new hoisting works are completed, and the engines, pumps, etc. ready to move. The main shaft has been newly timbered down to the 360-ft level, at which depth the oars are now running. Though the mill is kept steadily running, the pile of ore on the dump remains large, and the rock of a character highly satisfactory. In every respect the future of this mine looks very bright. During the month of December the mill, in twenty-seven running days, crushed five hundred and forty tons of rock, which yielded eight hundred and ninety-six and a half ounces of gold. John A. Townsend, the efficient superintendent, can well review the results of his efforts on this mine during the year just past, with pride, for from his management the new year promises to prove one of success for the company.

SAN BENITO.

SILVER PROSPECTS.—San Benito Advance, Jan. 8: The Mechanics' Strike is the name of the silver bearing ledge owned by Charles Sairs, Farrell and others, and located about twelve miles east of Hollister. The working force have sunk a shaft down about twenty feet, and by penetrating into the hillsides about eight feet through the drift they have struck a vein of promising ore. Several tons are now on the dump. A sample has been shipped to Grass Valley to be worked by the Fryer process. Large quantities of sulphur and arsenic have been found in the vicinity of the mine, combined with other mineral.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill News, Jan. 6: Daily yield 600 tons of ore, keeping the mills all running up to their full working capacity. Contrary to general expectation, the Consolidated Virginia mining company yesterday declared a dividend of \$10 per share on their capital stock, aggregating \$1,080,000, and payable on the 11th inst., thus, in the face of floods, fire and storms, continuing steadily to pour out its millions of treasure—strengthening, building up and sustaining, not only its own elevated character, but aiding, by its treasures and the encouragement it gives, the development of every other mine on this line of the Comstock.

OPHIR.—The repairs to the drifts and winzes on the lower levels are steadily advancing, and are progressing so favorably that the hoisting of ore will probably be resumed in about another week's time. The pumps and pumping machinery are working splendidly.

BELCHER.—Daily yield 450 tons of ore, all of which is being crushed by the mills as fast as it is extracted. The returns from the ore are good and the prospects are that the monthly yield will be increased instead of diminished. A dividend of \$1 per share, aggregating \$104,000, was declared on the 3d inst., with every

prospect of not only a continuance of the dividend, but a fair expectation of an increase in the amount.

NORTH CONSOLIDATED VIRGINIA.—This mine is attracting more than usual attention, from its location being on the direct course or tend of the immense ore deposits in the Consolidated Virginia, California and Ophir, and being situated only about 1000 ft to the north and east of the Ophir. In addition to this the shaft has reached a depth of 630 ft, at which point the management have determined to start their first drift to cut and prospect their ledges. The belief in the minds of many is strong that they will find a continuation of the rich ores of the Ophir still further to the northeast than it has yet been developed. The ravines in the vicinity of the North Consolidated Virginia shaft have been worked at intervals for years past for the gold they contained, and there is a prevalent and well founded belief that the source of this gold cannot be very far away. The machinery of the mine is in excellent working condition, and the developments are being pressed ahead with all the vigor possible.

JULIA CONS.—The main south drift on the 1400-ft level is steadily advancing, the face in low grade ore. Opening the 1600-ft station and drifts is making rapid headway, many fine seams of quartz and ore being encountered, while outting for the station. This work is being done in the best possible manner, none but the best of timbers being used in the construction of the station.

CHOLLAR-POTOSI.—Daily yield 70 tons of ore. The bullion shipments for the month of December amounted to about \$50,000. There is no material change in any of the ore producing sections of the mine.

SULLIVAN.—The station at the adit level, beneath the bottom of the shaft, being completed, a drift is now being run south from it, following a very eligible strata in the ledge matter. As several small veins of pay ore were passed through by the tunnel, it is expected that this south drift will develop a body of ore somewhere at this level. The prospects for finding a bonanza were never better in any mine on the Comstock than in this. After running about 300 feet south, following the vein, cross-cuts both east and west will be made, exploring the ledge from wall to wall, 180 feet.

KOSKUTH.—The winze 600 feet south of the main shaft is down 100 feet below the 200-ft level, the bottom having struck a flow of water so strong as to stop and prevent a continuance of the work until the water is drained by the main south drift on the 350-ft level. Pumps continue to handle the water with the most perfect ease, and everything in and about the mine works splendidly.

LEVIATHAN.—Sinking the main shaft deeper is being done at a lively rate. Some very promising veins of ore are now being passed through in sinking, all of which give good assays, being evidently feeders of the main ledge. In sinking this shaft deeper it is expected to cut the main ore vein developed at the 420-ft level, at the depth of 550 or 600 feet in case it preserves its regular pitch or dip to the eastward, which it doubtless does.

GLOBE CONSOLIDATED.—The prospecting drifts both north and south on the 350-ft level are steadily advancing with very encouraging results. When once the contemplated new pumping machinery is erected and in good working order the prospects of the Globe will be second to none of the prospecting claims on that portion of the Comstock.

OVERMAN.—The main west drift on the 1100-ft level has reached the east wall of the ledge, and will, in a day or so more, connect with the north drift from the bottom of the winze on the same level. As soon as this connection is made and ventilation obtained, cross-cutting the 1100-ft level will be commenced.

LADY WASHINGTON.—Owing to an accident to one of the hoisting reels work has been somewhat retarded, but the damage has been repaired and work resumed.

BALTIMORE AND AMERICAN FLAT.—The excavation for the large water tanks at the 1050-ft station is completed, and the putting in of the tanks is getting well under way. The machinery of the mine is in the finest possible working condition.

ORIGINAL GOLD HILL.—The south ore body shows improvement, not only in extent, but also in richer ore. The extraction continues at the rate of twenty tons per day, which is reduced at the Hope mill, Silver City. The first shipment of bullion to San Francisco from this mine last Saturday amounted to \$3,145, and the next regular shipment will be made Saturday. When increased milling facilities can be secured a corresponding increase in the bullion will follow, as there is any amount of ore in sight.

BULLION.—The north drift on the 1700-ft level is steadily advancing in very favorable ledge matter. Sinking the main incline is going rapidly ahead, the bottom in good working ground.

CALIFORNIA.—Sinking the C. & C. shaft is making excellent progress, the bottom in good sinking ground. There is but little being done in the way of developments on the lower levels, if we except a continuation of the north drift on the 1550-ft level toward the Ophir line. The face of this drift is still in good ore.

YELLOW JACKET.—The north and south drifts from the bottom of the winzes on the 1940-ft levels have been connected, and the men are now engaged in timbering the drifts. As soon as the timbering of the drifts is completed, cross-cutting on that level will be commenced.

CROWN POINT.—Daily yield 425 tons of ore, keeping the mills all steadily running. The

ore breasts show no encouraging features for the week, but continue much the same as for several months past. The prospecting drift south on the 1600-ft level is steadily advancing to connect with this winze from the level above. Sinking this winze is steadily going forward, the bottom in ore of a fine character.

LADY BRYAN.—The main north and south drifts on this 380-ft level are being steadily advanced, both affording more favorable prospects than for some time past. On this 250-ft level the south drift is showing some good ore.

NEW YORK CONSOLIDATED.—Raising the third compartment of the shaft is making excellent progress. The 800-ft level is well opened, and two drifts have been started, one east and the other west, to cut and prospect the ore vein. The face of both these drifts are in fine ledge matter.

DAYTON.—Two drifts, one north and other south, have been started on the 500-ft level.

NORTH OAKSON.—The air shaft connection being completed, good ventilation is secured, and the work is being pushed forward to better advantage than ever. The ore in the face of the north drift shows considerable improvement, the vein increasing in width and showing more black sulphurets and less of the copper stain heretofore met with. Sinking is resumed in the main shaft.

IMPERIAL-EMPIRE.—Daily yield 40 tons of ore. There is little if any change in the appearance of the ore, either north or south during the week. The north drift on the 2000-ft level is still in fine quartz, carrying apots and streaks of excellent ore.

SILVER CITY.—Work in this mine going ahead vigorously as usual. The ore is being stopped out above the main adit level and deposited at the dump for milling. A large amount of ore has accumulated on the dump, and the milling of it will be commenced soon. The working of the mine has been very systematically and effectively conducted under the present management.

JUSTICE.—At the 800-ft level the drift south shows well in low grade ore in its face. The stopes and breasts of the 400 and 600-ft levels are yielding about thirty-five tons per day of good paying ore.

SUTRO TUNNEL.—Some very fine stringers or feeders of quartz, or low grade ore, have been cut through during the week, giving assays from \$1 to \$7.25 per ton. The Burlington drills are doing splendid work, and the tunnel advancing at very fair rate. Total length last evening, 11,846 feet.

HALE & NORCOR.—Owing to a breakage of the pump-rod during the latter part of last week, but little work has been done on the lower levels of the mine. The damages are again repaired, and sinking the winzes on the 2200-ft level is again going steadily forward.

LEO.—The north drift at the bottom of the winze is still in quartz and ore of a very encouraging character.

COSMOPOLITAN.—Some bunches of ore, showing well in free gold, were met with in the north drift during the week.

PICTOU.—More streaks of quartz have been passed through this week, and the general appearance of the material in the face of the tunnel indicates still nearer proximity to the ledge.

KNICKAROOKER.—The flow of water is being gradually lessened by the pumps.

GOULD & CURRY.—Retimbering the shaft is going on steadily ahead; it is expected it will be completed in a few days more.

Colorado.

SPLENDID CHUNK.—Colorado Miner, Jan. 1: Mr. Edward Riley, the superintendent of the Stevens mine, recently took out a chunk of ore weighing 277 pounds, which has been forwarded to General Beverley R. Keim, of the Kansas Pacific railway, for exhibition at the Centennial. It runs 96 ounces in silver to the ton, and 73½ per cent. lead. We hope our miners generally will follow this example.

BOULDER COUNTY.—The Banner says that Messrs. Carvell have started crushing and amalgamating works four miles up Boulder canon. From the Banner's description we presume these works treat only nonrefractory surface ores.

New shaft houses are dotting the hillsides. Miners are all happy in the possession of winter jobs. The American mine building is completed. Mining property is lively.

The discovery of a valuable deposit of mica, three miles north of Sunshine, is reported. An eight-foot shaft reveals a four-foot vein.

Idaho.

REVIVAL OF BUSINESS.—Idaho Avalanche, Jan. 7: That there will be a general revival of business in connection with mining operations in this vicinity at an early day, there is now no doubt. Fairview, Wagonwain, South Mountain, Flint and other camps will present a lively appearance in a few months hence. Posey & Co. keep seven teams engaged in hauling rock from the Oro Fino, South Chariot and Belle Peck mines. The roads are in good condition. There is a great disappointment among the former employees of the Empire at the non-resumption of operations in that mine. Many of them would be quite willing to begin work and take their chances of getting pay from the rock that would be crushed, which is known to be quite rich. There will be another cleaning up from Belle Peck rock in a week or two, and a handsome yield is promised. Vigorous operations have been started at the Golden Chariot since the first of the year.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Quicksilver in San Luis Obispo County.

The San Luis Obispo Tribune says: Mining for quicksilver is becoming one of the leading industries of San Luis Obispo county. At the present rate of development it will not be long until the mines of this county will equal in production, if not surpass, that of any locality in the State. At the present time there are five companies in active operation, all making developments or shipping quicksilver in large quantities. There is the Oceanic, six miles from Cambria; the San Jose, El Rincon, and Tres Amigos, within eighteen miles of San Luis; the Sunderland, or, as more commonly called, the Lockhart mine, near Paso Robles; the Josephine, and last, though not least, the Ocean View mine, situated eleven miles east of San Simeon. In an interview with Mr. E. B. Burdick, superintendent of this mine, we learn the following facts: They have a body of ore developed for a distance of thirteen hundred feet in length and sixty-five feet in depth, with a width of one hundred and five feet. All of this immense body is pure ore, and will average not less than two and one-half per cent., or fifty pounds of metal to the ton of ore. This body of ore is equivalent to 443,625 tons, holding in its rocky embrace not less than a thousand tons of liquid metal. In the lowest depths of the mine yet explored, it is much richer, reaching six per cent. At a valuation of \$1,500 the ton for quicksilver, here is \$1,500,000. Allowing two-thirds of this amount as cost of production there is a profit of over half a million for the lucky owners of this mine, and one million to be circulated in our midst for labor and material. This estimate will be found considerably under the mark if any curious person should go over our figures, allowing twenty cubic feet for a ton of ore.

Having fully demonstrated the value of the mine the company are now busy with the erection of a first-class furnace and extensive hoisting works. Mr. Luis Janin, late of Virginia City, Nevada, has the contract for building the furnace, which is modeled after the Oceanic, with improvements designed by Mr. Janin. The machinery for the furnaces and hoisting works are all at San Simeon. Mr. Burdick in company with P. A. Forrester, Esq., of Cambria, came to town on Friday of last week, to engage teams to go and haul the machinery to the mine before the heavy rains of winter set in. He engaged seven six-horse teams which have gone up for the work. The hoisting works will be modeled after the latest and best in the land. The working shaft is to be of three compartments, two for hoisting and one for pumping.

The mine is situated in a heavily timbered country, and thus far a team has not been used for delivering their lumber from the saw mill to the works. They have a steam saw mill capable of cutting all the lumber they will ever want. The timber is a large yellow pine, many of the trees being three or four feet in diameter, and squaring two feet for sixty to seventy feet in length. Water is abundant for all purposes connected with the mine and reduction works. The company has built a grade from San Simeon to the mine, a distance of eleven miles, at a cost of \$5,080. The heaviest grade is only nine feet in one hundred. The road was surveyed by H. C. Ward, civil engineer, and constructed under the direct supervision of Mr. Burdick. He employed sixty men, and was 22½ days in completing it. It is said to be the best mountain grade in the country.

The company is incorporated in San Francisco, H. K. Moore being the President, and D. Buck Secretary. Among the heaviest owners in the mine are Messrs. F. Greenman and C. W. Kellogg, President of the Merchants' Exchange bank, of San Francisco. The company has applied for patents for its mines—there being four belonging to the company—and Mr. R. Harris has gone up to survey them. This is but a mere sketch of this enterprise, but must suffice until we get time to spend a week in and about Cambria, when we hope to do that section of country ampler justice than we have been able to heretofore.

Effect of Color on the Sensations.

Having recently achieved the luxury of a new carpet in our sitting room, we are all quite surprised at the effect the accidental but judicious distribution of colors in it has over feelings and sensations.

The quality is the ordinary ingrain, and the pattern a very old-fashioned one, of large, wavy green and bright crimson fern-shaped leaves on a white background, there being but three colors, white, red and green. The effect is one of indescribable warmth and comfort, such as never was experienced before, but is noticed by every one who comes into the room.

This hint is worth attention in the selection of carpets. What the result will be in hot weather remains to be seen. A little judicious selection and discrimination in such cases makes more difference than an ordinary unobservant person would suppose.

The same is true of wall papers, neutral tints, such as buff and violet being much cooler than more positive colors, such as bright crimson, green, etc.

Light colored or white hoods make the feet appear larger than black. Longitudinally striped clothing causes the person to seem much taller, while lateral stripes have the contrary effect.—*Ex.*

The Sierra Flume Company.

Some two or three weeks since the Plumas National intimates that the route for the Chipman-Hayward flume, from the Sierra mountains to the navigable waters of the Sacramento, was not yet decided upon, and that it would go by one of the two routes, viz: Down the North fork of Feather river, or from the foot of brave, bald old Lassen down Deer creek. Supposing the bulk of the timber looted by this company last summer to be in the vicinity of the Big meadows, we had supposed the flume for its transportation to the Sacramento valley would be down the North fork. But we understand that the surveyors found grave difficulties to be overcome along that turbulent stream, and that it has been determined to construct the flume on the Deer creek route. There is said to be no inconsiderable portion of their timber located in close proximity to this line of flume, and as it presents a much shorter and cheaper route, it has been adopted for their line of the flume. We learn these facts from Mr. Abbott, of the Big meadows. The company have already purchased from Mr. Gerko, of the Gerke ranch, some ten miles above Chico, a piece of land suitable for a dump for their timber.

The land lies on the Sacramento river, to which point their flume will extend. This will give the company water carriage from the point where the timber grows, to the markets of the world, and at the cheapest possible outlay, and must give them a tremendous advantage in the principal markets below, while they have the choicest timber region in the world to cut their timber in. During the summer season the lumber can be rafted down the Sacramento at a very trifling expense, and will be about equivalent to running a saw mill at Sacramento with plenty of timber at hand to work upon. As we have before remarked, while commenting upon this subject, this will be highly beneficial to the company, but will not prove remunerative to the section of country providing the timber. We believe it practicable to construct a railroad over the Deer creek route to the Big meadows, and cannot repress the regret that the company has determined to build the V flume, which does nothing but carry away, instead of the road. But it was not for us to say. The company have, probably, consulted their own interest in the matter, and chosen the cheapest way to get the timber to the markets of the world, leaving the region furnishing the timber to become productive after their operations of gathering the timber are over, or remain good for nothing. A railroad would carry in as well as bring away, and might make the country around Lassen as famous as the Alps of Switzerland, as it deserves to be.—*Butte Record.*

Carp Culture.

A little more than three years ago J. A. Poppe arrived in this State from Rhinefeldt, Holstein. A part of his baggage was a lot of small carp, five in number and six inches long. He began at once a system of carp culture, following the experience of the German carp farmers. He put his five small carp in the water at Sonoma, in August, 1872; one dying and four surviving in the new habitat. In the following May the fish had grown to sixteen inches in length and had given life to three thousand young fish. Since that time these fish have grown rapidly, and Mr. Poppe assures us that he finds sale for all his marketable fish at one dollar a pound. Mr. Poppe is at present desirous of extending the business of carp culture among those who have facilities for it, and is prepared to furnish the stock for beginning. He sends us the following items concerning the practice:

In Germany thousands of pounds of this favorite fish are raised and sold every year. The farmers there who are engaged in pisciculture have from five to seven ponds. The smallest is the breeding pond, from which the others are stocked. The contents of one pond are sold every year. Numbers of fish are floated down the rivers and canals in large boxes pierced with holes, through which the water passes in and out, thus delivering the carp to the consumer alive and fresh. They are a fish that need but little attention, are hardy, prolific, and do excellently on this continent. Their food may consist of wheat, barley, corn, peas, bran, blood, sour milk, or in fact almost anything. When well fed they will grow one inch per week for the first two or three months, after which they will grow slower in length but increase rapidly in weight. It will not do to breed them in ponds where any game fish are kept, as they will eat the young carp.

Farmers who have natural facilities on their places for making ponds, and who have access to canals or rivers communicating with large cities, can greatly increase their income with but small trouble and expense. There ought to be one person in every county who would raise choice carp as stock fish to sell to others to fatten for their own tables. It would be a cheap but sumptuous food, and at the same time very convenient, as they are ready to be eaten at all times of the year.

Mountain Lands.

Mr. Luntrell's bill in Congress and Mr. Ferral's move in the Legislature of this State seem to very fully embody the popular feeling on the subject of the proper mode of opening up the mountain lands of California to permanent occupation by bona fide settlers. The State Grange, P. of H., also, at their late meeting, endorsed the proposition so far as to allow actual settlers the privilege of locating 640 acres of such lands for homesteads and for grazing purposes.

It is certain that under the present laws these lands can never be brought into market so that the title can pass to any large extent. They consist chiefly of broken ranges, thinly timbered in the foothill lands, springy watered and wooded everywhere, and producing only light crops of native grasses. There are but few locations where the settler can select a quarter section, the chief part of which shall be suitable for cultivation. By far the larger portion is suitable only for grazing purposes. But if these lands were surveyed and set off in tracts of 640 acres or more—in no case less—and offered to settlers at a reduced price, the theory is that every tract would contain some little valley, with springs or rivulets, where the settler might make his home, cultivate a little patch for a garden, raise a few roots or perhaps cut a little grass to tide his stock over the few weeks that intervene between the destruction of feed by the early rains and the springing up of the new grass, which appears soon after, and thus utilize the great bulk of his claim for grazing purposes.

On the contrary if they are segregated into 160 acre tracts, the section which contains the valley and water privilege will be taken up, while the 480 acres will be worthless to any other person, and will be left unsold, and consequently unimproved to any great extent, for the reason that no one will pay the price required for a title. The consequences will be loss to the Government, imperfect development of the agricultural resources of the entire district and constant differences between neighbors who will each strive to get the advantage of the other in their efforts to use the unsold tracts which lie between their respective properties.

Four-fifths of the land at present unsurveyed in the foothills is now enclosed with rough fences by parties holding the small watering places, without yielding any revenue to the Government; while even the best portions of such lands are but imperfectly utilized by reason of the uncertainty of the tenure.

Mr. Luntrell's plan of throwing them open to purchase in tracts of 640 acres (or more if necessary) at the minimum price of fifty cents an acre, would soon result in the establishment of numerous well built homesteads and well cultivated tracts of land, on which vegetables and to some extent cereals, also vines, fruit and timber trees might be successfully grown, but the outlay for which cannot be afforded under either the present minimum price of \$1.50 per acre, or the uncertain tenure of a settler's title when the future contingency of legislation is uncertain.

If the law making power had set itself at work to devise some way to prevent a proper development of the foothill lands no more perfect plan could be devised for such a purpose than that now in existence. Some legislation is an imperative necessity in this direction. The only questions in that regard should be that of securing the benefit to actual settlers, the proper extent of the tracts into which the land should be segregated (from 640 to 1,280 being the extremes named), and the price per acre—fifty cents being the minimum figure which has been suggested. Of course no legislation should be made which would interfere with the rights of minors on the mineral sections.

The adoption by Congress of some plan of this kind will no doubt greatly facilitate the settlement of these lands, which constitute a very extensive area, and the permanent occupation and improvement of which would create a large amount of taxable property to aid in supporting the fast increasing expenses of our State Government.

A SERMON IN A PARAGRAPH.—President Porter, in Ysle, gave the following advice to the students of that institution the other day: "Young men, you are the architects of your own fortunes. Rely on your own strength of body and soul. Take for your star self-reliance. Inscribe on your banner, 'Luck is a fool, Pluck is a hero.' Don't take too much advice—keep at the helm and steer your own ship, and remember that the art of commanding is to take a fair share of the work. Think well of yourself. Strike out. Assume your own position. Put potatoes in a cart, go over a rough road, and the small ones go to the bottom. Fire above the mark you intend to hit. Energy, invincible determination with a right motive, are the levers that move the world. Don't swear. Don't deceive. Don't read novels. Don't marry until you can support a wife. Be in earnest. Be self-reliant. Be generous. Be civil. Read the papers. Advertise your business. Make money and do good with it. Love your God and fellow men. Love truth and virtue. Love your country and obey its laws."

A Company's Liability for Kissing by an Employee.

In the case of Craker against the Chicago and Northwestern company, the Wisconsin Supreme Court has given its decision. The plaintiff, a lady, took passage on a train on the Madison division, and the conductor of the train, while on the journey, forcibly kissed her. She brought suit against the company in the Circuit Court, and got a verdict of \$1,000 damages. The case was appealed, and now the Supreme Court decides as follows, the decision involving some important points:

A master is liable for a wrong done by his servant, whether through the negligence or the malice of the latter, in the course of an employment in which the servant is engaged to perform a duty which the master owes to the person injured.

It seems that the master should be liable in all cases for the servant's wrongful act done in the course of his employment, whether through negligence or malice.

A railroad company is bound to protect female passengers on its trains from all indecent approach or assaults; and where a conductor on a company's train makes such an assault on a female passenger, the company is liable for compensatory damages.

Exemplary damages cannot be recovered against the principal for a wrongful and malicious act of the agent, neither authorized or ratified by the principal.

A verdict of \$1,000 damages for the insult offered by defendant's conductor to the plaintiff in this case, held not so excessive as to authorize the court to set it aside.

THE THUMB AS AN INDEX OF CONTEMPT.—Scott says to hit the glove or the thumb was a horrid pledge of mortal revenge. In England thumb biting was practiced to goad an adversary into fighting. Dekker tells us that St. Paul's walk was notable for shouldering, jeerings, and hitting of thumbs to beget quarrels, and Shakespeare imports the fashion into Verona. When Gregory and Sampson espy two Montague men, out fly their swords; but prudent Sampson, to compel the others to take the initiative, bites his thumb at them, "which is a disgrace if they hear it." Challenged with the question, "Did you bite your thumb at me, sir?" he replies, "No sir, I do not bite my thumb at you, sir; but—I bite my thumb!" and in a few minutes the fray begins. It was not absolutely necessary to put the thumb to the mouth. In 1291 a rude fellow was sent to prison for casting vile contempt upon the clerk of the sheriff of London, by raising his thumb and saying, "Iphurt, Iphurt!" "in manifest contempt of our Lord." If one Neapolitan wishes to anger another, he places the palm of his right hand on the back of the left, and shakes the crossed thumbs, symbolical of donkey's ears, at him; a pleasant hit of pantomime answering to the "taking a sight" popular elsewhere—a sign of contemptuous defiance, said to be at least as old as ancient Assyria.—*All the Year Round.*

DIFFERENCE BETWEEN CYCLONES AND WHIRLWINDS.—In a memoir on cyclones and waterspouts, M. Monchez publishes some observations made by him while upon the ocean, and which, if correct, are quite important. According to his account, at or near the surface of the ground the current of air in the cyclone is always from below upwards, while in whirlwinds the movement is, on the contrary, from above downward. In the former case, the winds are winds of aspiration; in the latter case, the winds descend from the cloud in the form of a hag or tube, which terminates in a point. M. Monchez is consequently led to believe that waterspouts have no relation whatever to cyclones, having, in fact, opposite appearance and cause, an opinion in which some other scientists occur.

LEWIS DISTRICT.—This district is about thirteen miles from Battle Mountain and contains several fine mines. The mill, owned by Hildreth & Co., A. Evan, Wm. Humphrey and others, is of ten stamps with capacity for twenty, is running upon the ore from that district. They have on their own dump over two hundred tons of fine rock, working from \$100 to \$800, and are extracting not less than \$12,000 worth of this quality of ore daily. The tunnel on their mine is now in about 500 feet, and they have ore enough in sight to last five years. The mill is a new one, just being erected, and will be in running order and is expected to be set in motion this week.—*Humboldt Register.*

THE BREAKING UP OF LARGE MASSES OF IRON, has, as our mechanical readers are well aware, been a matter of considerable difficulty and expense. This is, however, according to the *Moniteur Scientifique*, now accomplished in the case of large guns, by placing dynamite at the lower end of the gun and filling the bore with water. The explosion of the dynamite, transmitting its force through the water, fractures the gun.

MORE PLANETS.—A German astronomer has discovered two new small planets, not visible with the naked eye, in the constellation *Aries*. This makes the number of the lesser planets one hundred and fifty-three.

BOSTON has a woman newspaper carrier who is 87 years old.

USEFUL INFORMATION.

Re-seating Chairs.

Cane seated chairs are very apt to wear out and then, if their owners are far from the upholsterer, they are thrown aside as useless. Any woman with a little ingenuity can repair them so they will be "good as new." Take any piece of bagging or burlaps—no matter how coarse—and fit them to the chairs, cutting them large enough to wrap about the rounds that hold the splints or canes. Now sew it on with the darning-needle and twine twice doubled, and turn up a hem, as you sew on the burlaps. When half fitted, stuff it with "excelsior" shavings of poplar wood; or if you have them, cut off layers from old quilts, and spread them smoothly over the chairs, under the burlaps. The layers of cotton can be tacked together before they are put in, and then they can be laid more smoothly upon the old canes. Fine hay will also answer for stuffing when nothing better can be procured. Now sew down the other two sides, and take pieces of carpeting, or of enameled cloth, or colored rep, or all wool dress goods, and tack them closely down with large silvered or brass headed nails, which come for the purpose, and behold! your chairs are far handsomer and more comfortable than before. The materials have, possibly, cost you but little, for many an attic would furnish them all but the nails, which must be procured at the upholsterer's. Gimp to match the ground color of the cushion, or even worsted braid, is desirable to place along the edges of the covering, and drive the nails directly through it. This makes a handsomer finish to the cushion.—*Exchange.*

VALUE OF THE COMMON BROOM PLANT AS A FIBER.—The common broom plant is announced as furnishing a fiber equal, and in some respects superior, to that of hemp and flax. In view of the great extent to which this plant occurs wild in Southern Europe, and the ease with which it is cultivated, such applications, not indeed new, but only more recently revived, promise important results. Its fiber can be very minutely divided, and as it retains heat, it can supply the place of wool. It receives the most delicate dyes as well as an animal fiber, and successfully resists the action of acids and salt water without undergoing any change or losing its tenacity. Its strength is one-third greater than that of hemp, while it is thirteen per cent. lighter. It can be furnished, delivered at the factories, for about £2 per ton. The fiber may be obtained by soaking the stems for a few days in warm water, or else by means of a chemical solution of little cost.

TO AVOID WET FEET.—Here is another way to prevent water from getting through shoes. The composition also makes a good harness dressing. Take neatfoot oil, one and one-half pints; heesewar, one ounce; spirits of turpentine, four ounces; and stir until cold. Spread and rub this composition over the leather while it is damp; leather will absorb oil and grease better when damp than when dry. For the soles, take pine tar and rub it in before the fire until the soles will absorb no more. Three or four applications will be needed. The durability of the soles will be much increased. If this preparation will do what is claimed for it, it will be invaluable to miners, who are now compelled to suffer from wet feet, or endure the almost equal danger and inconvenience from the constant use of rubber boots in wet weather.

A CANE WITH A CANDLE.—A very simple walking cane, with a candle enclosed, which might be convenient for use in dark passages, or even for reading in railroad cars, has been invented by a German. The top portion consists of a hollow cylinder screwed on, and containing a spring to press upward as fast as consumed, a candle in it. It is closed by a screw cap, which forms a convenient top.

HOW TO USE POSTAL CARDS.—Anything whatever, except an address, written or printed on the side intended for the address renders postal cards unmailable, and the same cannot be legally forwarded unless prepaid at the letter rate—three cents. But if, by inadvertence, it reaches its destination without such prepayment, it is chargeable with double the letter rates, minus the one cent originally paid for the postal card.

PLATING COTTON WITH SILK.—A method of covering cotton with silk has been devised. The silk is dissolved in hydrochloric acid, or an ammoniacal solution of copper or nickel. Water is added until the solution begins to cloud, when the cotton, previously mordanted, is immersed in it for a few minutes. When taken out it will be found to be plated with silk.

TO REMOVE GREASE SPOTS FROM PAPER.—Warm the paper and cover it on both sides with dry, finely ground pipe clay, and place it under a slight pressure for a few hours. Then dust off the clay, and remove the fine dust that still adheres by means of a good piece of India rubber.

In 1840 the first experience in photography was made in Paris by Daguerre.

Oil colors will adhere to cement if primed with boiled linseed oil.

Apparatine—A New Anti-Incrustator.

A new anti-incrustator has lately been introduced under the name of apparatine, which is prepared by stirring up 16 parts of potato starch in 76 parts of water, and then adding eight parts of potash or soda lye, at 25° Baume, the whole to be thoroughly mixed together. In a short time the mixture forms a thick jelly, and it is then beaten up vigorously for a time, when it forms a colorless, transparent substance, slightly alkaline to the taste, and of a strong glue-like consistency. It dries slowly in the air, without decomposition, and when perfectly dry resembles horn, but is more flexible. When introduced in small quantity into steam boilers it prevents their incrustation. It is also capable of nearly all the applications of ordinary gelatine, and is especially adapted for sizing textile goods of all kinds, imparting to them a hitherto unattained smoothness. When applied to goods and dried it is perfectly insoluble, as three or four washings in hot water have proved to have no effect upon it. It can also be used as a thickening in calico printing. Several of the technical journals speak of this substance as a very important addition to the resources of the manufacturer and dyer. Care must be taken to retain it in air tight vessels until it is used, as it is not easily rendered soluble again when it once becomes hard.

NEW LOCOMOTIVE ATTACHMENT.—Among the recent novel American inventions is one which is described as consisting of a telescopic arrangement of tubes projecting from the front of a locomotive engine, and so arranged that when pushed in by contact with any object—a cow on the track, for instance—a valve is opened, and a series of projectiles are thrown out, which quickly remove the obstruction. The *Engineer*, commenting on this product of American genius, suggests as an improvement that the tubes be replaced by a projecting spar, to the end of which a torpedo might be attached, which may be exploded by electricity under the least, and so accelerate its movement!

PATENT LEATHER.—Newark, N. J., produces most of the patent-leather made in this country, and we import none of this kind of goods except patent calf-skins. Our manufacturers have pushed their goods into the foreign markets, and have succeeded in competing with foreigners in their own countries. This branch of business has hardly felt the dull times, owing to the fact that it depends so largely on the foreign market. The manufacture was begun in Newark, in 1813.

GOOD HEALTH.

Health of Farmers.

The Massachusetts Board of Health is out with its fourth annual report, in which is to be found an interesting paper on the longevity of the farmer's life. It says the evidence collected from country physicians throughout the State for the last twenty-eight years, shows that the average length of the life of a farmer in that State is fifty-five and a fourth years. This is much longer than that of any other class of citizens. The class most nearly approaching farmers, viz., out-door mechanics, live only fifty-two and a half years on an average.

The almost unanimous belief of those physicians and the compiler of the paper is, that farmers might live much longer than they do, by exercising more care in choosing, cooking and eating their food, in avoiding overwork and exposure to change of weather, and the use of foul drinking water. Their food consists too much of pork, pies and saleratus bread and cakes. The cookery is bad and meals are eaten too quickly for good digestion, when work hurries. More vegetables and fruit should be eaten, and more rest taken. More cleanliness as regards out-houses, sinks and backyards, should be observed, and more care taken to avoid leaving cess-pools, sinks, etc., nearer to a well than thirty feet at least.

DRY AND CRACKED FINGERS.—The *New York World*, in answer to a correspondent says: We know, by experience, something "about dry and cracked fingers," for we once worked on a farm and was careless, as many men and boys are, about properly cleansing our hands. It was our own fault that we had sore hands, as it is yours. We finally learned to avoid the suffering by washing our hands clean with castile soap and hot water and wiping them dry before exposing them to the cold air. Before going to bed at night we used to rub them with glycerine and dry it in before the fire. We never had any trouble afterwards. If at our work we got our hands wet when they were dirty, we took pains to rub them dry as soon as we could before exposing them to the air.

BEEF FOR DIPHTHERIA.—A young lady was recently attacked with diphtheria in a virulent form. Slices of fresh pork were bound on her neck without any good results. Her father heard that the city doctors were using beef extensively for the same purpose, tried it, and in six hours the beef turned green, relieving the sufferer.—*Ex.*

PERFECT SLEEP.—The sleep of perfect rest is dreamless—a kind of sleep not produced by laudanum, chloral or any other drug. Remember this, young people, at the beginning of your lives. Do healthy work enough to weary you, and you will sleep a healthy sleep, and be doubly sure of a good old age.

Death in the Dishcloth.

A lady says in the *Rural World*, when some of you are sure to be down with typhoid fever; when neighbors are neglecting their own work to nurse you; when doctors are hunting in cellars and old drains for the cause, let me whisper in your ear—look to your dishcloths. If they be black and stiff and smell like a "bane-yard," it is enough—throw them in the fire, and henceforth and forever wash your dishes with cloths that are white, cloths that you see through, and see if ever you have that disease again. There are sometimes other causes, but I have smelled a whole houseful of typhoid fever in one "dishrag." I had some neighbors once—clever, good sort of folks; one full fair of them were sick at one time with typhoid fever. The doctor ordered the vinegar barrels whitewashed, and threw about forty cents worth of carbolic acid in the awl-pail and departed. I went into the kitchen to make gruel—I needed a dishcloth and looked about and found several, and such "rag!" I burned them all, and called the daughter of the house to get me a dishcloth. She looked round on the tables: "Why," said she, "there was about a dozen here this morning," and she looked in the woodbox and on the mantelpiece, and felt in the dark corner of the cupboard. "Well," I said, "I saw some old, black rotten rags lying round and I burned them, for there is death in such dishcloths as these, and you must never use such again."

I "took trams" at nursing that family four weeks, and I believe those dirty dishcloths were the cause of all that hard work. Therefore, I say to every house-keeper, keep your dishcloths clean. You may wear your dresses without ironing, your sun-bonnets without elastics—but you must keep your dishcloths clean. You may only comb your head on Sundays, you need not wear a collar, unless you go from home—but you must wash your dishcloth. You may only sweep the floor "when the sign gets right," the window don't need washing, you can look out at the door; that spider web on the front porch don't hurt anything—but, as you love your lives, wash out your dishcloth. Let the fox-tail get ripe in the garden (the seed is a foot deep any way), let the holes in the heels of your husband's footrags go undarned, let the sage go ungathered, let the children's shoes go two Sundays without blacking, let two hens set four weeks on one wooden egg—but do wash out your dishcloths. Eat without a tablecloth; wash your faces and let them dry; do without a curtain for your windows, and cake for your tea—but for heaven's sake, keep your dishcloths clean.

PREVALENT ERRORS WITH REGARD TO APOPLEXY.—A medical authority writing to the *New York Tribune* regarding the death of Vice-President Wilson, corrects one or two very prevalent errors with respect to apoplexy. The symptoms of this disease, so dreaded and so sudden in its attacks, are due to a lack of proper supply of blood to the brain, and not, as is generally supposed, to an accumulation of "rush of blood to the head." The rupture of the cerebral blood-vessels is due to weakness of its coats, which is the result of general debility or ill health. In the great majority of cases there are no premonitory symptoms. The attack may be preceded by a sense of weight or fullness, vertigo, flushing, etc., but these symptoms are never to be relied on. The liability to an attack increases progressively from the age of twenty years and upward. Another popular error is that persons with short necks, florid faces, and full habit are peculiarly liable to this attack. Recent researches develop the fact that the majority of persons attacked are either spare or of ordinary habit of body. Physicians conclude that unless one attack has occurred there are but few, if any, physical signs or premonitory symptoms which will warrant the prediction of an attack in any case.

CARELESS HANDLING OF CHILDREN.—I wish to enter a protest in the name of all nervous persons and of the injured little ones against the reckless way in which many heedless persons express their love for children, such as lifting them up by their heads, tossing and catching them in the air, carrying infants on their hands without any support to their backs, and otherwise endangering their limbs or senses. I have now in my mind the case of a man who was rendered a cripple for life through his father's carelessness in lifting him by the ankles, while he was a small child, he (the father) having unfortunately lost his balance and turned the child's ankles in such a way that he was lame ever afterward. Two different persons have told me that they knew when too late that by their thoughtless play with them they had seriously injured infants entrusted to their care, one case resulting in spinal disease and the other in fits. And yet it is a sight daily to be seen, that of people doing these things. Do give the little folks tender handling!—*Rural New Yorker.*

REMEDY FOR RHEUMATISM.—A correspondent of the *New York World* sends that journal the following: Here is a remedy for rheumatism I have tried in my family and found most excellent for inflammatory rheumatism—it is a charity to print it: Four ounces saltpetre in one pint of alcohol; shake well and bathe parts affected; wetting red flannel with it, lay it on. It does not cure, but takes away the redness, reduces the swelling, and relieves the torment and agony.

DOMESTIC ECONOMY.

Different Ways of Preparing Cabbage for the Table.

An excellent cold slaw is made by shredding a solid head of cabbage with a thin, sharp knife, or a slaw cutter, then placing the cut cabbage in your dish, pour over it a dressing made by heating a pint of vinegar scalding hot, then heating into it quickly one beaten egg, with a lump of butter as large as a walnut, and a tablespoonful of sugar. The cabbage should be slightly sprinkled with salt and pepper as it is put in the dish.

To fry cabbage, chop or shred quite fine, have a spider bot on the stove, in which is a small quantity of batter or meat drippings, season, and put in the cabbage, and cover tight, stirring often and taking care it does not scorch on the spider. Cooked in this way it is very sweet and nice.

Cabbage makes a nice dish also cooked by dropping into salted boiling water, and when tender taken out, minced fine with a knife, then pouring over it a dressing made by taking a piece of butter the size of an egg, and a coffee cupful of boiling water; cut up the butter with a half teaspoonful of flour, and stir it gradually into the hot water. When it boils, stir in a dessert-spoonful of vinegar, and a dash of pepper, with a little salt. For the sauce, thick sweet cream is an excellent substitute.

For hot slaw prepare the same as for cold slaw, cook tender, and pour over the dressing, or merely season with vinegar before dishing up.

Somebody has said that corned beef with boiled cabbage makes the best three hundred and sixty-five diamers a man can eat in a year. To realize the full measure of excellence the quality, curing and cooking of the beef should be considered, but with this, I have nothing in this letter to do. Perhaps some sister can give us directions by which we may secure perfection in this part of the process. As to the cabbage, have a solid head stripped of the outside leaves, except one layer, divide it into quarters by gashing down nearly through to the lower end of the core. Skim the floating grease as nearly as you can from the top of the water in your boiling pot of beef, and about one hour before dinner time drop in your cabbage and keep it boiling steadily and slowly until you are ready to dish it. Now, carefully lift it out with a skimmer and lay on a platter, draining well, take off the outside leaves left, and your cabbage will come out clear and free from grease or scum.

A NEW PROCESS OF MAKING BREAD.—M. Cocil, a French engineer, has invented a new process of preparing the materials for making bread, which has received the approval of the minister of war and will hereafter be adopted in the French army. By this process an increased percentage of the nutritive properties of grain is retained, so that by avoiding the usual grinding and wetting, the grain that would make 115 pounds of bread in the ordinary way will make what is equivalent to 140 pounds. The new process is described as follows: The unground grain is first steeped in water, after which it is placed in revolving cylinders, by which it is deprived of its outer husk, which contains but four or five per cent. of nutriment. The grains are then softened by forming them into a thin sponge, and keeping them for a space of six to eight hours at a temperature of seventy-seven degrees Fahrenheit. They are then crushed under and made into dough, with salt and water, as usual.

BAKED BEANS.—Many people do not understand how to make nice baked beans. One of the most serious troubles is, they don't give them time enough to bake. Bake them slowly all day Saturday, and if convenient let them stay in over night, baking full twenty-four hours, and our word for it, your beans will come out in the morning smoking, with a flavor that will make your mouth water to taste them, and your breakfast will be the best you ever had. We sometimes see persons who only have a moderate liking for baked beans, who invariably bake them three or four hours, and that is why they do not like them any better. A day and a night is none too much time to bake these excellent, having parboiled them only a few moments, until the skins will crack when the air comes to them.

VEGETABLES.—These should never be washed until immediately before being prepared for the table. Lettuce is made almost worthless in flavor by dipping it in water some hours before it is served. Potatoes suffer more than any other vegetable through the washing process. They should not be put in water till just ready for boiling.

ORANGE PUDDING.—Four sweet oranges peeled and picked to pieces and put in a deep pudding dish with two cups of sugar. Put a quart of milk, the yolks of three eggs, and two dessert-spoonfuls of corn-starch on to boil. Take off, cool it, and pour it on the oranges. Then beat the whites to stiff froth, put it over the pudding and place in the oven until it is of a light brown color.

TO CLEAN A NURSE.—Take a wooden bucket, fill it half full of wheat flour. Then dip your nubia up and down in the flour until it looks white, shake thoroughly, when it will be as nice as new, and not have the drawn appearance which washing gives.

The Mining Debris Question.

We give in this issue the proceedings of the mass meeting of citizens of Sutter and Yuba counties in relation to the mining debris question. We also give the preamble and resolutions offered in the legislature by Assemblyman Berry, of Sutter, on the same subject. It is hardly probable that any decisive steps will be taken in the matter at this session of the legislature, but it will be very generally discussed. The miners have the best of it, from priority of rights and general established custom; and it is probable that the agriculturists have, in a measure, injured their cause by the exaggerated figures presented at the mass meeting. The miners, as yet, have not considered the opposition of sufficient importance to require an answer, but our columns are open to those who wish to bring facts in their possession before the public. The question is a very important one and no hasty steps should be taken.

JOHN SINNAMON, late superintendent of the Ames iron works at Oswego, N. Y., has gone to Albina to assume the same position in the Oregon iron works, which manufacture portable and farm engines.

Bullion Product of 1875.

The very gratifying increase in production of precious metals for the year just past by States and Territories west of the Rocky mountains is something wonderful. From year to year the production increases, while from year to year people continue to deny mining and mining interests. It is only when the annual returns come in that this class of people are not heard from. The returns this year are \$6,487,982 in excess of 1874, as will be seen from the following report of John J. Valentine, superintendent of Wells, Fargo & Co.'s express.

EDITORS MINING AND SCIENTIFIC PRESS: We enclose you herewith a copy of our Annual Statement of Precious Metals produced in the States and Territories west of the Missouri river, including British Columbia and the West Coast of Mexico, during 1875, which shows an aggregate yield of \$80,889,037, being an excess of \$5,487,982 over 1874, the greatest previous annual yield in the history of the Coast. Nevada, Colorado, Mexico, Oregon, British Columbia, Montana and Arizona increased, while California, Idaho, Utah and Washington decreased. The increase is actual except for Mexico, Oregon and Arizona, where it is apparent rather than real, as compared with other years, a regular product being accounted for and reported herein, hitherto omitted. The decrease in California was in the main occasioned by a stinted supply of water for placer and hydraulic mining. The increase in Colorado and Nevada is notable, also the fact that Nevada yields more than half of the whole product of the country. Prof. E. W. Raymond credits New Mexico (omitted in our statement) and Arizona combined, with \$387,000 which is a liberal allowance. We have been unable to obtain any data that justifies a showing so favorable. Present prospects indicate an aggregate yield of \$90,000,000 for 1876, of which Nevada will doubtless produce \$50,000,000. Respectfully yours,

J. J. VALENTINE, General Superintendent.

Statement of the amount of Precious Metals produced in the States and Territories west of the Missouri River during 1875.		STATES AND TERRITORIES	Amount
California	\$14,422,010	Gold Dust and Gold Bars	\$14,422,010
Nevada	196,883	Gold Dust and Gold Bars	196,883
Idaho	739,133	Gold Dust and Gold Bars	739,133
Utah	1,135,338	Gold Dust and Gold Bars	1,135,338
Montana	2,268,000	Gold Dust and Gold Bars	2,268,000
Arizona	4,388	Gold Dust and Gold Bars	4,388
Colorado	22,500	Gold Dust and Gold Bars	22,500
British Columbia	2,227,444	Gold Dust and Gold Bars	2,227,444
Mexico	68,117	Gold Dust and Gold Bars	68,117
Total	1,015,412	Gold Dust and Gold Bars	1,015,412
	\$23,049,861	Gold Dust and Gold Bars	\$23,049,861
	\$2,099,402	Silver Bullion	\$2,099,402
	\$1,080,287	Silver Bullion	\$1,080,287
	\$13,450,274	Platinum	\$13,450,274
	\$30,880,067	Platinum	\$30,880,067
	\$74,401,065	Platinum	\$74,401,065

Nevada again heads the list and California comes second. The increase in Nevada over 1874 is \$5,026,146. The decrease in California has been \$2,547,380; Oregon has gained \$455,976; Washington has decreased \$73,603; Idaho has fallen off \$325,102; Montana has gained \$134,111; Utah has fallen off \$223,784; Arizona has gained \$83,028, although we do not consider the figures from that section as reliable as others, as so much bullion goes through private hands, of which Wells, Fargo & Co. would have no account. Colorado has gained \$2,108,412; Mexico has gained \$1,609,773. The figures from Mexico cannot be considered as full as they should be for the reasons given concerning Arizona. British Columbia gave \$140,396. The total increase of all over last year amounts to \$6,487,982. This is a most gratifying showing. Nevada has had a chance to get ahead of all by her wonderful bonanza on the Comstock, and it is expected that the increase will be still greater from that section next year. We shall have more to say on this subject in our mining review in the next issue.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'S SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

PROCESS OF LEVELING LAND.—THOS. R. LOWE, Centerville, Fresno county, Cal. The object of this invention is to provide a simple and effective process for leveling uneven or hilly land for agricultural purposes, in order to render it susceptible of being more easily irrigated and cultivated so as to produce crops of a uniform growth. Much of our agricultural land lies in hills and hollows, so that a large portion of the work of plowing, sowing and reaping must be done to a great disadvantage on side hills, while that portion of the crop which grows in low places is generally stronger and more thrifty than what is grown on the higher land, and for this reason: Much more labor is required in harvesting than if the crops were uniform throughout.

Mr. Lowe's invention contemplates reducing this kind of land to one general level by means of a stream of water forced against the hills or

higher portion of the land, so as to wash it into the hollows and thus produce a level surface out of what was before hilly and uneven.

In carrying out this invention Mr. Lowe uses water, which has been placed by nature or by artificial means, at a sufficient elevation to provide the requisite pressure. This water is conducted through hose to the proper place. There levees are thrown up wherever it may be necessary around the tract of land, and at intervals in these levees are constructed gates, which can be opened when desired. The stream of water is then applied against the hilly land, either by water pressure or engine, until the higher portion is loosened up and reduced to the consistency of mud, and then a large quantity of water is turned into this mud, so as to carry it to the lower land or hollows, and thus bring the entire surface to a uniform level.

PHOTOGRAPHIC BACKGROUNDS.—I. W. TABER and THOS. H. BOYD.—This invention consists in the employment of a stationary wire screen in front of a canvas background, for the double purpose of protecting the canvas from injury and providing a compound background picture. The wire cloth has painted upon it a portion of the scene which is to be employed as a background picture. The painting thus delineated should not fill the meshes or interstices of the wire cloth, so that when the photographic background is produced upon the card, it will have a peculiar softness, owing to the rays of light passing through the meshes of the cloth, and striking the opaque or dead-colored canvas screen behind it. A very convenient arrangement, and one which will produce beautiful effects can be obtained by painting a fixed scene upon one portion of the wire screen, while the remaining portion is of a flame color, and then painting the canvas with a picture opposite the plain portion of the wire screen, and an opaque or dead color opposite the painted portion of the wire screen, thus producing a combination screen that can be changed by substituting other canvas screens with other paintings behind the wire, so as to retain the permanent design of the wire screen, thus providing a variety of views with the same main feature or foreground. The wire screen will then protect the canvas from injury, while it is not liable to be injured itself.

LEVER AND RACK FOR GANG PLOWS.—DANIEL KENDIG, Napa City, California. This invention relates to certain improvements in the operating levers and racks for gang plows, by which the inventor is enabled to do away with the strong spring heretofore needed to hold the lever to its place, where the rack was made upon the side, and the consequent necessity of considerable strength to operate the levers. In all plows in which two levers are used, one of the levers works about a center which is not the same as the center of motion of the other. As a consequence, this first lever must have a sliding motion up and down as it moves along the rack, and the rack was put upon the side and a long catch upon the lever was necessary to hold it at different points. By reason of the strong spring which holds the lever against this rack the operator must not only push the lever forward or back, but also press it strongly to one side, which is a difficult operation. In this improvement the rack is made on the top of the semicircle. The lever is attached to the lower end in the usual manner and passes up at one side of the semicircle. The strap which guides it passes over the semicircle, and has an arm extending up along the lever to near the top, where another strap clasps the lever. These two straps and their connecting arm will retain their relative positions in moving forward and back upon the semicircle, while the lever will be free to slide up and down, and accommodate itself to the varying center of motion. A nail to engage the rack is used.

WATCH CLEANING FLUID.—A. MONNIER, Sacramento. This is a compound for cleaning watches and other jewelry or other mechanism, (which contains no silver,) without the aid of a brush or any friction, with alcohol or chalk, or other substances, thereby preventing the wear which is usual in such cases and cleansing much more perfectly and with less time. The fluid can be used for brightening and removing corrosion from steel, brass or gold jewelry and other articles. It is of especial value in cleansing watches with nickel movements, and by its use the damaging wear of the ordinary method is avoided. With it a watch can be thoroughly cleaned of rust, grease and foreign substances in twenty minutes, more easily than can be done in two hours by the ordinary process.

LAND DECISION.—In the case of H. W. R. CROUCH, agricultural claimant against sundry mineral claimants, involving the title to twenty acres of land near Grass Valley, California, the Commissioner of the General Land Office has rendered a decision of general interest to mine owners and agriculturists in the mining regions. He holds that the land in question must be excluded from Crouch's pre-emption entry, because, although it is not mineral land, it is of little, if any value for agricultural purposes, and is essential for the proper working of deep gravel mines in its vicinity.

The bullion product of Park county, Colorado, for the past year, was over \$1,000,000.

The Fryer Process.

The Mining and Railway Register, of St. Louis, has found a "mare's nest," and "exposes" the Fryer process by publishing an extract from the Patent Reports, describing what it supposes to be the process. The *Alta* of this city copies the remarks of the *Register*, prefacing them with the following paragraph: "Large promises have been made by this invention, and it is everybody's wish that it will prove a success. But if the remarks below are correct, then the sooner any such humbug is exposed the better for the community and the mining interests. These remarks are taken from the *Register* bearing date of December 30th."

"Much mystery has been affected by certain parties concerning what has gained some notoriety as the 'Fryer process.' If there is no more of it, or in it, than what may be found in the subjoined description of the patent just issued, we would expect nothing from it but mortifying failure and needless loss of money. There is nothing presented herein but an attempt to imitate the 'Spencer process,' in which Spencer failed so completely eight years ago in St. Louis. Volatilizing the precious metals from gangue matter, and recovering by condensation, will not answer. It's old, and a failure."

"170,625. Apparatus for roasting gold and silver ores, Robert M. Fryer, New York city, N. Y., assignor to the Fryer Noble Melting Company, of New York. The fuel and quartz are fed in through the door. The heat of combustion generates steam in the jacket, which passes up, and issuing through a circular perforated pipe in the stack, causes a draft. The metallic fumes, as the issue from the furnace, are condensed by water falling from the cone, and are collected in the upper water jacket. The movable bottom is lowered, and carries the reduced charge to any point desired."

It happens, however, that this is not by any means the 'Fryer process.' The patent above mentioned is simply that on the furnace used by Mr. Fryer in the preliminary steps of the process. His condensing apparatus is only intended to catch such fumes as may attempt to escape, but he does not attempt to volatilize all the metals from the gangue, and then condense them. Instead of using a blower to force a draft in his furnace, he uses a steam jet to draw the air through. Instead of using a separate boiler to generate this steam he gets his steam from the water in the water jacket of the furnace. There is nothing of any very great novelty in the general arrangement of the furnace, but the details of construction make it effective for the purpose for which it is intended.

So, instead of the patent No. 170,625, given above, being the Fryer process, it is simply the furnace used in the preliminary stages of the process. The ore is afterwards worked by a peculiar system of dry amalgamation, which has not yet been made public. It will be time enough to pass judgment for or against the process when the details are made public, so that some intelligent opinions of its merits can be formed. For the present unfavorable criticisms are hardly fair, for the hearsay condensation of its working, (all most of us have 'to judge from,') is undeniably favorable; when it shall transpire that the promoters are endeavoring to swindle the community, or that their assertions are unreliable, it will be time to expose the game. So long, however, as they pay their way honestly, ask money from no one, put up big works, and do what they say they will, they undeniably have a right to a respectful hearing, which should be awarded to them.

OUR EDITORIAL ROOMS.—The editorial and composing rooms of the Press have, for the past two weeks, been in a state of almost hopeless confusion, and we are just beginning to get settled again. Carpenters, whitewashers and painters have run riot in our sanctum, but although their presence was a nuisance at the time, the result of their labors has made a great difference in the appearance of the office. The compositors, pressmen, mail clerks and assistants now have more commodious and convenient quarters, and the editors pride themselves on the improved appearance of the sanctum. The editorial rooms have been divided off by partitions, so that each writer has a "box" by himself, where the conversation of others will not annoy him. The partitions and other wood work glisten brightly with a handsome coat of Averill chemical paint, which has been well put on, and which changes entirely the appearance of the rooms. They are now light and airy, and the glossy appearance of the paint makes everything shine and look cheerful. What the painters did with the dust we do not know; but it has all disappeared, and with it a ton or more of pamphlets, papers, etc., which have been accumulating for several years. We now have our library in order and conveniently arranged. The entrance to the editorial rooms has also been changed, and we no longer have to pass through the composing room. The noise of the presses and machinery is, moreover, deadened by the partitions, so the rooms are quieter and better adapted for the purpose for which they are intended. When our friends from the interior favor us with a call, we can now show them as comfortable and convenient editorial rooms as there are in the city. As we feel pretty happy over it, we couldn't help telling our readers of our luck.

The Mining Debris Question.

The most important business in the Legislature on Saturday was the presentation by Assemblyman Berry, from Sutter, of a preamble and set of resolutions on the question of mining versus agriculture, which has lately given rise to some controversy between important sections of the State. Following are the preamble and resolutions:

To the Senate and House of Representatives of the United States, in Congress assembled:

First—Your memorialists, the Legislators of the State of California, respectfully represent to your honorable body, that the system of hydraulic mining, as now prosecuted upon the headwaters of the Sacramento river, the Feather river, the Yuba river, the Bear river, the American river and numerous other smaller streams, all of which flow into the Bay of San Francisco, is having the direct effect of covering up all the rich alluvial lands of the upper Sacramento valley to a depth of from one to twenty feet with an unproductive debris, thereby destroying many millions of dollars in property, and rendering desolate the homes of hundreds of actual settlers.

Second—We would further represent that at this time, from the immensely improved appliances in use for said hydraulic mining, and the construction of immense reservoirs and numerous ditches rendering water for such mining purposes cheap, hundreds of miles of gravel silt and beds are now being and will be washed down upon our valleys that heretofore would not pay for mining. In fact, this process of mining is yet in its infancy, having been in operation but about fifteen years. It is thought by those competent to judge that in the next twenty years it will increase manifold.

Third—We would further respectfully represent that most of the above named streams have already been filled to their highest banks with gravel, sand and mountain debris, and that all the cereal-producing lands in the upper portion of these valleys are already destroyed, and that many of our beautiful cities and towns are almost annually inundated; that our Capital city and magnificent State House are threatened with speedy destruction, and that unless the threatening danger is speedily averted the most inviting and productive valleys on the continent will be rendered wholly uninhabitable.

Fourth—We would further represent that upon the Yuba river there have already been destroyed and abandoned twenty-four sections of land, which to-day in its primitive condition would be worth more than \$2,000,000; thirty-six sections on Bear river, worth \$1,500,000; sixteen sections on Sacramento river, worth \$750,000; eight sections on Feather river, \$500,000; ten on American river, worth \$600,000; twenty-two on other smaller streams, \$1,000,000; total, \$6,350,000. This is a destruction of lands alone; the improvements that have been destroyed and the personal property that has been driven away from those lands, would amount to as much more, to say nothing of the depreciation of adjacent property, and the general retardation of the prosperity and business enterprise of our State.

Fifth—We would further represent that our farmers in the locality of these streams have for a number of years past been building and constructing a succession of levees and embankments along the margin of the low lands adjacent to those streams at a cost of more than two million dollars, and that the inhabitants of Sacramento have filled in and raised the business portion of said city to a height of fifteen feet, and have surrounded the entire city with an embankment of the same height. This work cost more than one million dollars. That the city of Marysville has expended hundreds of thousands of dollars in surrounding herself with a series of embankments, notwithstanding which, less than twelve months ago, she was inundated, and suffered the loss of more than a million of dollars, and to-day the bed of the Yuba river is at a higher elevation than her streets, and its waters are kept off them only by a narrow embankment of earth; and that other towns and villages have already and are yet expending vast sums of money in resisting the encroachments of the water and debris; and that the inhabitants of the above cities, towns, villages and localities have been and are now taxed to their utmost tension, hoping to preserve to themselves and families that portion of our villages not yet entirely and irrevocably destroyed. The result of all their efforts has been temporary, precarious and insecure protection, an exhausted treasury, and total destruction in the near future. Experience has taught them, and demonstrated most clearly that they cannot remove the debris from the rivers and water courses and raise embankments as fast as the process of hydraulic mining fills them up. They find themselves helpless, and, without aid, cannot much longer escape destruction.

Sixth—We would still further represent that our navigable rivers, the Sacramento and the Feather, upon which we are dependent for cheap fares and freights, are about destroyed—so much so that they can only be used in high stages of water, thus depriving us of the highways furnished by nature, which are indispensable to our prosperity, and forcing us to adopt more costly means of transportation.

Seventh—We would further represent to your honorable body that the bay of San Francisco, the finest harbor in the world, is menaced. T. J. Arnold, engineer of the State Board of Har-

bor Commissioners, has estimated that debris is being washed into the bay in sufficient quantity to cover annually one square mile to a depth of forty-one feet, and that it will take but fifteen years to fill Suisun bay, and but thirty-one years to complete the destruction of San Pablo bay, after which the bay of San Francisco proper is the only receptacle left for the entire debris washed from the mines.

The above estimates are founded upon the discharge of debris that is actually now occurring. When we consider the wonderful improvements already made and likely yet to be made in the process of hydraulic mining, we realize that the mountains are literally moving down into our valleys, rivers and bays. Wherefore your memorialists pray that the foregoing statement of facts may receive at your hands that attention its importance demands. Believing that no one industry should be fostered to the utter annihilation of other and paramount interests, therefore be it

Resolved, By the Assembly, the Senate concurring First, that our Senators in Congress are instructed and our Representatives requested to place this memorial before Congress and to press the matters therein mentioned respectfully upon their attention.

Resolved, Second, that our Senators be instructed and our Representatives requested to favor the amendment of the present laws so that no mineral lands shall be disposed of by Congress for the purpose of hydraulic mining, only upon such conditions as shall prevent injury and damage to the valley lands, rivers and bays of our State.

Resolved, Third, that our Senators be instructed and our Representatives requested to urge upon Congress the adoption of such measures and the passage of such laws as shall prevent the destruction of our rivers and bays, and keep them open to that free navigation which is indispensable to our prosperity as a State.

Resolved, Fourth, that our Senators be instructed and our Representatives requested to urge upon Congress the propriety of sending to this coast a competent engineer for the purpose of collecting information as to the extent of hydraulic mining, and the amount of

damage done and likely to be done thereby to our valley lands, rivers and bays, and obtain such other information as may be pertinent to the subject, for the purpose of laying the same before Congress at a subsequent session.

Resolved, Fifth, that his Excellency Governor Irwin be respectfully requested to forward without delay a copy of this memorial and these resolutions to each of our Senators and Representatives in Congress.

Carpenter—I move the reference of this memorial to the Committees on Mining and Agriculture, and that, for the purpose of its consideration, they be made and constituted a select committee.

Berry seconded the motion, which was adopted.

POISONED BY WEARING GUM BOOTS.—The Walla Walla (W. T.) Spirit says: Dan Gillman, an industrious teamster, returned recently from a trip to Boise, dangerously poisoned by the imprudent wearing of gum boots. His whole body was at one time covered with a solid scab, and his suffering on the road was truly heartrending. At one time his life was in jeopardy, but through the assistance of medical aid from Baker City and the kindness of Jo Wadsworth, a fellow-teamster, he was at length enabled to reach this city, and is now fast recovering. Mr. Gillman was severely poisoned in a like manner near Colville about two years ago, and his blood seemed to be still impregnated with impure matter. Gum boots are not to all persons injurious, yet they should be used at all times with due discretion.

THE erection of the new machinery on the Utah mine is nearly completed, and it will not be long now before the pumps will be ready to clear the shaft of water and enable the resumption of work again on the lower levels.

By the fall of a bank in a mining claim near Volcano, Amador county, last week, J. Alamy was instantly killed, and a man named Williams seriously injured.

ALTA, Utah, threatens to take out \$5,500,000 worth of gold and silver ore this year.

New Ore Crusher, Grinder and Amalgamator.

Charles Brads, of Copperopolis, Calaveras county, has patented through the agency connected with this office some improvements in crushing, grinding and amalgamating ores. It consists principally in the combination of crushing wheels with a series of drags within a circular track. From this track the pulverized ore is carried into a flume or sluice box containing a series of peculiarly constructed riffles, where it is amalgamated.

The circular grinding track has a suitable surface for the purpose, and made of large diameter. A vertical shaft stands in the center of the elevation within the circle, and to the lower end of this are attached the arms for the attachment of animals for driving the machine. Other arms are arranged to drag the crushing wheels within the track as the arms are driven around. To the arms to which the animals are attached are also fastened the drags which follow the rollers around, and by this combination of rollers and drags the ore is crushed and pulverized to the requisite degree of fineness.

One opening is made at a certain point in the side of the outer rim of the pan which encloses the track, and provided with a suitable screen through which the pulp passes as fast as it becomes fine enough. This pulp, together with sufficient water, is carried by a trough or pipe to the sluice box, into which it falls and passes over the peculiarly constructed riffles. These riffles consist of inclined planes

THE "ECONOMIZER" ENGINE.

which this inventor makes about four feet long by one foot wide, and having a rise of about one inch to the foot. From the top of each incline the water and pulp fall down the abrupt face to the foot of the next plane, and thus through any number of planes. The mercury for amalgamation is placed in the space at the front of each flume, and is partially retained by means of the inclines, but the falling of the water into these spaces as above described is apt to carry some of the valuable metal up the inclines, and it will eventually pass out from the sluice and be lost.

In order to prevent this Mr. Brads employs plates, which are placed across the flumes and stand at an angle, their upper edges being advanced beyond the lower edges. These plates are so placed that the water and pulp fall from the top of each incline into a space between the face and the plate, and all eddies, currents and splashing take place within this space. From this the pulp is forced down through the mercury into which the edge of the plate just dips, and then gently flows up the incline with no tendency to carry off mercury or amalgam. By this device the inventor states that he can save so closely that he is unable to find any trace of mercury or gold in the tailings below the sluice. The sluice may be placed close against the side of the grinder, or, as will be most convenient, it can be set at a short distance away and connected by a pipe or trough so as to leave room for the horse, which drives the crusher, to pass easily. Of course the use of wheels, rollers or drags running in a circular track are not claimed as new, they being commonly used in the Chilean mill and arrastra, both of which are as "old as the hills."

VERY encouraging reports reach us from Central district. All the mines now being worked are looking well. The Teamster, on which work has recently been resumed, is producing the richest kind of ore.

THE Victoria Colonist claims the gold yield of the provinces for 1875 as amounting to \$2,490,026.

The Economizer Portable Engine.

In all the various manufacturing interests of our country, there has long been a want of a simple but effective engine for light work, that can without delay be changed in motion and in amount of power used; saving, at the same time, a proportionate amount of fuel, thus enabling the printer to run on or more presses—the jewelry manufacturer to run on or more machines—the cabinet maker to run on or more lathes—the cheese maker to run part or full capacity—the blacksmith or wagon maker to run on or more forges or machiasses, at proportionate cost for fuel and attention. The "Economizer" is put into the market to fill this want, and is claimed to be very effective in varying supply of fuel to supply of power. The manufacturers use a horizontal boiler, made of heavy boiler iron, having all the merits of a stationary boiler, requiring no mason work, ready for use when shipped, doing away entirely with the dangerous "fire box" and "crown-sheet" of ordinary portable boilers, yet having all their portableness; also having more heating surface than the same size of the common upright boiler.

We give on this page an illustration of the engine applied to agricultural purposes. In our advertising columns is a small portable engine such as we describe. It is placed on top of the boiler, the shaft end of which is bolted on outside of the flue sheet, thus taking off all steam from the boiler, and is also so constructed that, at any time, it can be removed from the boiler and placed upon a sagin foundation, at any point near or remote from the boiler. A prominent feature of the engine is an adjustable cut-off, which can be adjusted without delay, cutting off the steam in the cylinder at any point, and holding it back in the boiler for the next revolution of piston; varying at the same time the strokes of the pump piston, proportionately cutting off the supply of water to the boiler, and enabling the operator to use such amount of power as may be from time to time needed, with proportionate amount of fuel.

The piston rod is of the best English steel, made smaller than of common wrought iron, to equalize steam area on both ends of piston. The piston rings are double steam expanding, presenting a narrow surface for friction—a simple but very effective way of getting rid of the old fashioned piston bolts and set nuts—that are liable (unless adjusted by a machinist) to throw the piston out of the center of the cylinder. Brass stuffing box glands are put in the cylinder head and steam chest, preventing the piston rod and valve stem ever coming in contact with iron; thereby preventing entirely the crasing so often seen in engine piston rods and valve stems, and is a great saving of friction and packing.

The engine bed is cast in trunk shape, the strongest form in which iron can be made; at the same time light and shapely. The pump is attached to the bed instead of to the engine cylinder, which prevents the heating of this pump and valves, which so often renders the working of the pump uncertain. The crank shaft is made of one piece of hammered iron or steel in the strongest form, and runs in Babbitt metal bearings, in boxes that are cast solid on engine bed and cylinder head.

Every engine is furnished with a band pulley, besides the balance wheel, Judson's improved governor, a patent adjustable cut-off, a reliable pump, safety valve, steam gauge, suction and feed pipes, blow-off pipes and cocks, try cocks, glass water gauge, brass check valves, and stop cocks to keep water out of pipes when not running, and to prevent freezing in winter.

The boiler and casing, or arch is made entirely of boiler iron. The heads are made of best flange iron, thoroughly braced. There is a good hand hole, of easy access, to clean the boiler readily. The fire is built as in ordinary stationary boilers, under the front end, the heat passing under the boiler to the back end, and returning through the flues to the front end, escaping through the bonnet cast on the boiler front, into the smoke pipes. By this arrangement is secured the largest amount of heating surface, water and steam room, with the greatest economy of fuel. A wrought iron casing or arch is securely bolted in the center of the boiler, lined with fire tile, thereby preventing loss of heat by radiation, permitting the use of coal, shavings or coarse wood. It is worthy of remark that the feed water pipe is so arranged that water is thrown into the boiler below the flues, thus preventing any danger of explosion, unless the boiler is entirely empty.

A most important advantage is in its being so simplified that an unskilled person can, with directions sent with each machine, operate it with ease and safety. These engines and boilers are made in Syracuse, New York, the agents here being A. L. Fish & Co., Nos. 9 and 11 First street, where they may be examined.

THE Colorado Central lode, near Georgetown, has developed a body of ore, three feet wide, at a depth of 180 feet, a low grade assay of which runs 700 ounces, and adjacent to it another vein has been discovered, which the owners are confident will prove the largest pocket in the Territory.

Lorn Puscasse, of England, has purchased the London mine, in Park county, Colorado, from Ford & Smith, for \$300,000.

OFFICE AND ADDRESS,

No. 168 TEHAMA STREET,

Cor. Third, bet. Howard and Folsom, San Francisco.
eowbpAt a Stated Term of the Circuit Court
of the United States of America of the Ninth Judicial
Circuit in and for the District of California, held
at the court room in the city and county of San Francisco,
on Thursday, the 30th day of September, in the
year of our Lord one thousand eight hundred and sev-
enty-five. Present—The Honorable Lorenzo Sawyer,
Judge.Nicholas Seibert, complainant, vs. Wm. T. Garratt,
defendant—In equity.

DECEED.

This cause came in to be heard at the February
Term, A. D. 1875, of this Court and was argued by
counsel and thereupon upon consideration thereof, it
was ordered, adjudged and decreed, as follows, viz:
That defendant, William T. Garratt, was not the first
or original inventor, or discoverer of the improvement
or discovery claimed by him, in and by those certain
reissued letters patent of the United States, number
five thousand three hundred and twenty-eight (No.
5328), for an alleged new and useful improvement in
lubricators, issued to said defendant, William T. Gar-
ratt, on the 18th day of March, A. D. 1873, and is not
entitled to a patent therefor, and that said reissued
letters patent, number five thousand three hundred
and twenty-eight (No. 5328) are declared void and the
same are hereby vacated and set aside by reason of their
interference with those certain letters patent of the
United States, number one hundred and eleven thousand
eight hundred and eighty-one (No. 111,881) for a
new and useful improvement in lubricators, issued to
complainant, Nicholas Seibert, on the fourteenth (14th)
day of February, A. D. 1871.It was also further ordered, adjudged and decreed
that complainant do have and recover of and from de-
fendant his costs and expenses to be taxed herein.
(Signed) LORENZO SAWYER,
Circuit Judge.The above decree has reference to "Seibert's Eureka
Lubricator" for oiling the valves and cylinders of
steam engines.It has a glass gauge and condensing pipe, or reser-
voir, with a regulating feed valve, and works as fol-
lows: As the water of condensation is admitted, under
the oil, just so fast the oil passes out at the top through
a pipe into the steam pipe to oil the valves and
cylinder.Parties who infringe or purchase the infringing
lubricators, will be held strictly responsible.N. SEIBERT, Patentee,

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Suppl. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness of first cost, increased crushing capacity, time saved in changing and in setting tappings, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

DRILLING MACHINES.

PORTABLE DRILLS. Driven by power in any direction, self-feed and convenient adjustment.

RADIAL DRILLS. Self-feed—large adjustable box table—separate base plate, every convenience.

VERTICAL DRILLS. Self-feeding—of new and improved designs.

MULTIPLE DRILLS. For boiler work, etc., 2 to 20 spindles, fed and returned by power or hand, together or separately.

HORIZONTAL BORING AND DRILLING MACHINES. For large pieces—with boring head, adjustable, vertically and horizontally.

SPECIAL DRILLS. For special work. Gun Blank Drills, Coal Drills, &c., built to order.

AUTOMATIC PUMP.

SOMETHING NEW.

RAISES WATER BY COMPRESSED AIR.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.

By Special Dispatch, Dated Washington, D. C., Jan 11th, 1876.

FOR WEEK ENDING DECEMBER 28th, 1875.*

PADLOCK.—Geo. R. Cutbirth, S. F., Cal.
BOOTS AND SHOES.—William Biddle, Corvallis, Oregon.

PROCESS OF LEVELING LAND.—Thomas R. Lowe, Centerville, Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

"TRADE TUITION."—On Saturday evening, A. S. Hallidie, President of the Mechanical Institute, delivered the inaugural lecture of the course under the auspices of the University and the Institute. The subject, as previously announced, was "Trade Tuition." The progress of technical education in the United States and in the most enlightened countries of Europe was reviewed. The labors of the Art Association in this city in the establishment by it of a School of Design were complimentarily referred to. James Lick's beneficence in giving so liberally toward the founding of a School of Mechanic Arts was eulogized, and the unity of action between the Lick and Horace Hawes Chamber of Industry trusts urgently recommended, which the speaker believed would go far toward bringing about a solution of the problem of trade tuition in this city.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

SERVIA AND SLAVONIA M. Co.—January 8th. Location: Delano district, Elko county, Nevada. Directors—Wm. Holden, Henry P. Irving, John Garber, Charles E. Abbott and Samuel A. Morrison. Capital stock, \$100,000.

RISEING STAR G. & S. M. Co.—January 9th. Location: Garden Valley mining district, El Dorado county, California. Directors—George A. Gates, R. A. Wilson, J. W. Nye, P. H. Blake and C. C. Brookings. Capital stock, \$50,000.

MOUNT WASHINGTON S. M. Co.—January 9th. Location: California. Directors—John Banham, A. J. Kerslake, Wm. Jones, John A. Ransom and Charles W. Randall. Capital stock, \$40,000.

NORTH SIERRA NEVADA S. M. Co.—Location: Nevada. Directors—George W. Fisher, Charles E. Pearson, Daniel M. Seaton, A. J. Adams and John Ward. Capital stock, \$100,000.

LIVERPOOL G. & S. M. Co.—January 1st. Location: State of Nevada. Capital stock, \$50,000. Directors—C. M. Pease, Samuel Purdy, Robert J. Tobin, Samuel P. Middleton and George E. Sharp.

LONDON M. & M. Co.—Jan 7th. Location: State of Nevada. Capital stock, \$5,000. Directors—Wm. O. Pease, Samuel Purdy, R. J. Tobin, S. P. Middleton and G. E. Sharp.

MINDELEFF REDUCTION CO.—Jan 7th. Object, to mine for or to purchase and reduce copper or other ores, and to license to the Mindeleff process, United States letters patent, release, No. 6,509, on the royalty or any other system conducive to the welfare of the company. Directors—T. H. Alexander, L. L. Robinson, Demiry Mindeleff, James R. Smedberg, John Cornwell, J. Morgan and E. de F. Curtis. Capital stock, \$50,000. Wm. described the details of this process in a recent number of the Press.

CALIFORNIA SCHOOL OF MECHANICAL ARTS.—Jan. 10th. Object: To found, control and manage an institution to educate males and females in the practical arts of life, such as in wood, iron, stone or any of the metals, and in whatever industry intelligent mechanical skill now is, or can hereafter be applied; the institution to be open to all males or females born in California. Directors—J. D. B. Stillman, Horace Davis, A. S. Hallidie, John O. Eldridge, Lorenzo Sawyer, Horatio Stebbins and Wm. Aschburner. Capital stock, none mentioned. This is to be the institution provided for by Mr. James Lick. The gentlemen named by Mr. Lick to take charge of the matter met on the 8th inst., and elected those mentioned as Trustees of the Institute.

Meetings and Elections.

SAN FRANCISCO STOCK AND EXCHANGE BOARD.—James W. Coleman, President; C. W. Bonyage, Vice President; B. Howard Coit, Chairman; Henry Schmeddel, Treasurer; Franklin Lawton, Secretary; Thomas M. Blair, Sergeant-at-Arms.

PACIFIC STOCK EXCHANGE.—E. J. Baldwin, President; George S. Dodge, Vice President; Joseph Tilden, Chairman; George O. Hickox, Treasurer; A. J. Moulder, Secretary.

WASHINGTON G. M. Co.—Trustees: Richard H. Stretch (President), Thomas Wallace (Secretary), S. J. Corbett, Henry Sumner, and Merchants' Exchange Bank, Treasurer.

EMERSON CONSOLIDATED M. Co.—Trustees: H. B. Cogdon (President), W. C. Guirey (Secretary), Sias Sellick (Vice President), E. H. Rogers and H. F. Morris.

WEBSTER M. Co.—Trustees: Amos Roddy (President), W. S. Hopkins (Treasurer), E. Caldwell (Vice President), F. G. Berry, J. Scott Wilson (Secretary), R. P. Hosmer.

GILA M. Co.—Directors: A. K. Hawkins, Camilo Martin, J. M. English, J. B. McGee and K. Cohn. This company has been in trouble lately as some of the stockholders endeavoring to oust the trustees, who, however, were re-elected. On Monday the annual meeting of stockholders was held in the company's office in the Nevada block. The number of votes polled was 88,634. The present management received out of this number 60,624 votes against 23,494 for the opposition.

It is said that within the past few days the friends of the management took into the office enough shares to make up 32,000, thus enabling them to have a majority. The 8,624 in excess of the 62,000—making the 62,524 voted—were then all that the management had previously in its possession.

HUMBOLDT M. Co.—Trustees: A. Untz, J. Ginnace, G. B. Berry (President), D. Hardy and R. H. Brown (Secretary).

Mining and Other Companies.

Cherokee Flat Blue Gravel Company.

Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-eighth day of December, 1875, an assessment, No. 25, of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, room 13, Safe Deposit Building, No. 28 Montgomery street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid on the twenty-ninth day of January, 1876, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Saturday, the nineteenth day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. H. BOGART, Secretary.

Office, room 13, No. 323 Montgomery street, San Francisco, Cal.

Mariposa Land and Mining Company of California.

Location of works, Mariposa county, California.

NOTICE.—There is delinquent upon the following described stock, on account of assessment (No. 3), levied on the 30th day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,
BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam
Pumps were tried under every test known
to experts, the Examining Committee
of the Tenth Industrial Fair of the
Mechanics' Institute have
awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition,

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, [durability] and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim.

We are prepared to furnish PUMPS UNDER
CONTRACT, guaranteeing their ability to
perform any specific work for which
steam pumps are adaptable, such as

RAISING WATER FROM MINES,**FOR WATER WORKS,**

FEEDING BOILERS, RAISING WATER
FROM WELLS; STEAMER AND
SHIP PUMPS, ETC.

We would also call the attention of those
interested, to our Direct Acting Deep-Well
Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps
FOR HANDLING QUICKSILVER or heavy
liquids.

W. C. WILCOX & CO., Proprietors.**PACIFIC MACHINERY DEPOT,****H. P. GREGORY & Co., Nos. 14 & 16 First Street,****San Francisco, Cal.****P. O. Box 168.**

MINING ENGINEER.

A Mining Engineer, with the best of best of referen-
ces, thoroughly experienced in the opening and super-
intending of mines and mills, desires an engagement.
Address, "MINING ENGINEER," MINING AND SCIENTIFIC
PRESS Office, San Francisco.

Mining Superintendent

Of fifteen years' experience in working the most
rebellious ores on this continent, desires employment.
The gentleman thoroughly understands the opening
and development of mines, and the construction of
all kinds of machinery and appliances for the reduc-
tion of ores, and especially those termed rebellious.
Can be communicated with through this office.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of
the latest and most improved kind, and are again prepared
to fill orders for Rope of any special lengths and sizes. Con-
stantly on hand a large stock of Manila Rope, all sizes;
Tarred Manila Rope, Hay Rope; Whale Line, etc., etc.

DEWEY & CO'S
Scientific Press

Patent Agency.

Publishers, Patent Agents and Engravers.
No. 224 Sansome Street San Francisco Cal

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States, and the Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations of a descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

WORK AND COMPOSITION NAILS.

AT LOWEST RATES.

HENDY & COCHRANE'S ORE-FEEDER, FOR QUARTZ MILLS.

It is confidently believed to be the ne plus ultra of ore-feeders. One of these machines, on exhibition at the late Mechanics' fair, received the premium over all competing feeders. One was recently set up at Schnabel's mill in Newcastle, Placer county, Cal. It very soon showed itself to be the thing wanted; all other feeders under examination were at once rejected, and three more ordered for the same mill. We refer to the following mills using the Cochrane feeders: St. Patrick, Pugh, Green, and Julian, Newcastle, Placer county. Keystone Con. M. Co., Lincoln and Oueda mill, Sutter Creek, Amador county. Tybo Con. M. Co., Nev.

For description send for circular. J. HENDY, 32 Fremont Street, San Francisco, Cal., where it can be seen in operation. Also, manufacturer of Hendy's Improved Amalgamator and Concentrator and dealer in Quartz Mill Machinery and Machinists' Tools.

Harrison
New Haven, Ct.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

Number 4.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

BOILER AND FURNACE.—Joseph Enwright, San Jose. These improvements are especially applicable to portable engines, such as are known as threshing engines, but they can also be applied to stationary engines and boilers, where it is desired to burn straw, grass or other light fuel in the furnace for generating steam in the boiler. When straw or other light, quick-burning fuel is used under a boiler the feeding is continuous; consequently a very high degree of heat is maintained, which ordinary boilers will not stand for any length of time. Other difficulties also present themselves which must be remedied in order to render the utilization of straw as fuel economical. Mr. Enwright's improvements are intended to remedy the difficulties heretofore encountered in this class of engines and provide a superior threshing engine in which either wood, coal or straw can be burned.

BOX TRIMMING MACHINE.—Geo. W. Swan, S. F. This is an improved machine for trimming wooden boxes after they are nailed together, and it consists of a plane mounted between two vertical guides so as to be reciprocated up and down by a crank shaft and pitman in the rear of a table upon which the box is placed. After wooden boxes have been nailed together the sawed ends of the boards which form the sides are rough and generally project somewhat beyond the ends. Heretofore it has been usual to plane these ends off by hand, but by the use of the above described machine the box can be placed upon the table and the rough and projecting ends presented to the reciprocating plane so as to be cleanly and perfectly trimmed. This is another one of the numerous inventions made by Mr. Swan in his special branch of business, the box nailing machine that we have before described being probably the most important.

CONCENTRATOR.—James M. Thompson, San Francisco. This is an improved machine for concentrating and separating the heavy particles of pulverized ore and other finely divided substances from the light portions. The machine can be used for concentrating either wet or dry material. Any intelligible description of the machine is impossible without the aid of an engraving representing it.

MACHINISTS' TOOLS.—We illustrate on this page a twenty-eight inch swing lathe, twelve foot bed, made by the Kidd iron works, Rochester, N. Y. These lathes are all made in a very substantial manner, and are fitted with Gleason's patent tool post. With them is sold center rest, traverse rest, screw gearing, two face plates, counter shaft, cone pulleys, etc. With the Gleason tool post the tool can be elevated or lowered without loosening. It is also perfectly solid, and has the advantage of adjusting the tool without the double saddle, thereby enabling the operator to swing a larger diameter over the carriage than by the old plan.

OVER 10,000 people, coming from almost every State in the Union, have gone to the Black hills during the past three months.

The Fryer Process.

We received this week from Mr. W. A. Skidmore a number of samples of ore from different mines, showing its appearance in the various stages of the Fryer process. There is a quantity of sulphuretted rock from the Omaha mine, after roasting and ready for pulverization. In another package are samples from the same mine, showing the different classes of ore in a raw state, sulphuretted, crystallized and dead white. Samples of the same character of ore after roasting and ready for pulverization are in the same box.

In box No. 4 are samples of gold ore after roasting, from the Gold Run mine, Nevada county, showing the globules of gold. In box No. 3 is the pulp of this class of ore, after the roasting and pulverizing, prepared for amalgamation. It is in an extremely fine powder, and in a dry state. Another box contains tailings (roasted) from the Ophir mine. Samples of silver ore from San Salvador,

closely associated and do more and better work. A mining and engineering section will be immediately formed, some dozen or fifteen new members in that line having been proposed.

A resolution was adopted to the effect that the Academy should formally show its respect to the memory of the late Benjamin Parke Avery, U. S. Minister to China, and a member of the Academy, by attending the funeral in a body.

Charles F. Secor's Return.

His old acquaintances will be glad to notice the return of this gentleman to the Pacific coast. Mr. Secor was here as one of the earliest workers in the silver mines of Nevada, from 1860 to '64, but has been absent for years. We understand he claims the credit of having first applied steam to the reduction of silver ores, in 1863. We believe he is a thoroughly educated metallurgist; he has studied the science of metallurgy not only in this country, but in Swansea and in Freyhurg. He has been

Coral Islands.

On Saturday night last Professor Joseph Le Conte delivered the first of two lectures on the above named subject in Corinthian hall. These lectures are part of a series given by the State University and the Mechanics' Institute. The discourse was illustrated by maps and black-board drawings, and was divided into three parts, viz: First—The anatomy of the polyp, by whose agency reefs and islands are formed. Second—Coral branches, forests, reefs and islands. Third—The different theories regarding their appearance as a whole.

The construction of the polyp was elaborately explained, and also the various species of the same; the food used; how it was digested; its habits, growth, etc.; also the corallum, conditions of its life, etc.

Reefs were described as being divided into three classes, viz: The fringing reef, the barrier and the atoll. The gradual formation of each was illustrated, and their relation to each other described.

The theories respecting their formation was, perhaps, the most interesting portion of the lecture. The Professor gave as the first, the theory that coral islands were formed upon the craters and tops of submerged volcanoes, whose peaks came within the distance from the surface necessary to coral life (from 80 to 100 feet). But this, the lecturer contended, was an exploded theory, as some of the islands, barrier reefs and coral lagoons were as much as fifty miles across, and no volcanic crater could possibly be so large. The second theory was that of Darwin, and was undoubtedly correct, and had been received as such by the scientific world. It is this: Darwin con-

tends that the floor or bottom of the ocean has subsided, and is subsiding gradually. Suppose every reef to have commenced as a fringing reef. If the floor had remained stationary, the reef would always have remained a fringing reef; but the floor has gradually and slowly sunk downward. If it had sunk rapidly, the consequence would have been to have carried the corals down below their depth; but it went down so gradually that the corals were able to keep in breathing space of the surface—within the conditions necessary to their life. The theory is confirmed by investigation, for the space in which these reefs and islands are not found in the Pacific is first surrounded by small islands; second, the atoll; third, the barrier, and finally by a ring of fringing reefs. This completely explains the Darwin theory; the fringing reef marks the margin of the depression.

In concluding his remarks, Professor Le Conte said: Every atoll reef marks the spot of a drowned volcanic island, and is literally a monument erected by these mound builders, surmounted by a snowy chaplet of coral and a wreath of green trees.

THERE was a heavy snow-slide at Silver Mountain last week, at the Exchequer mine, burying three workmen, one of whom, William Bartle, was fatally injured by crushing in the hoisting works. Fortunately the engineers were at dinner, or they would have surely been killed, for all the machinery was completely covered. Nothing can be done to restore the works at present, as there has for some time been no possible communication with the mine, except by snow shoes.

TWENTY-EIGHT INCH SWING LATHE, TWELVE FOOT BED.

Central America, before treatment, were received, and also samples of the same class of ore after the preliminary roasting, showing globules of native silver. We shall be happy to show these various samples to those who are interested in this subject, a number of persons having already examined them.

We desire to inform our readers, moreover, that we will in our next issue give a detailed description, with illustration, of the furnace used in the Fryer process. The engravers were unable to complete the cut in time for this number, but public curiosity on the subject of the furnace may be gratified next week. As soon after as convenient we will illustrate and describe the other apparatus used in the process, Mr. Fryer having given us permission to do so.

California Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last. Little of general interest transpired. Vice President Edwards read a paper on Pacific Coast Lepidoptera, (No. 16,) being one of a series on this subject. Dr. Gibbons presented a memorandum of the dates, number and locality of earthquakes occurring in December, stating that they had been very frequent in various parts of the globe.

The committee appointed to consider the matter of sectionizing the Academy presented their report, giving their plan in detail, which was adopted. The idea is to form sections in the various branches of science, by which the workers in any special department will be more

practicing and testing the reduction of metals for twenty years, as we have been informed, and he now comes to this coast for the purpose of introducing an amalgamator for the reduction of gold and silver ores, which is the result of this experience. He claims that he can reduce the most of gold and silver ores by the application of steam, at an expense not to exceed three dollars per ton. The economy of the process is the most important part of it. We have not seen Mr. Secor's amalgamator and cannot therefore speak of it from our personal knowledge. He enters the field of discovery simply as a competitor for public favor and public patronage. If his discovery has not the merit which he claims for it, of course it will not receive encouragement. In the reduction of metals success is the only test of merit with any machine or with any process.

We understand that Mr. Secor will soon be ready to give a practical test of his machine, and we therefore welcome him to the field of competing inventors and discoverers, and we commend his amalgamator to the most careful examination of our mining experts and our most skillful metallurgists. We expect to notice the machine in detail as soon as an opportunity is afforded us.

THE work of extending the Utah Northern railroad is steadily progressing and the grade is nearly completed, ready for the ties, ten miles beyond Franklin, while considerable work is being done on the next five miles to the mouth of Bear River canon, and the tunnel and approaches will probably be completed by spring.

CORRESPONDENCE.

Hydraulic Gold Mining in California.

[No. 6.—Written for the Press by C. J. Brown.]

MESSRS. EDITORS:—Again, after a silence of many weeks, caused by circumstances and conditions beyond my immediate control, I take up the subject of my letters where I left off with a promise to pay my respects to other mining companies operating in this vicinity. The first that claims my attention is the

Polar Star

Hydraulic mining company, a California corporation, with its principal place of business at San Francisco; all the stock is owned by substantial business men of financial means. It is the owner of the claims once known as the American, the Buckeye, the Phoenix and some smaller tracts, embracing sixty-five acres, and covering the Dutch Flat channel from rim to rim at its inlet, or, in other words, at the upper or northeastern end of the deep gravel deposit on this channel. The surface bench of gravel was washed off many years ago, and the claims have lain idle ever since. Except the Buckeye, none of the ground on this end of the channel has ever been drifted. It was all worked as early as 1857-8, which continued actively for eight or ten years. The Buckeye has been quite extensively drifted, and formerly paid its owners large dividends. It was owned by a company of Welsh miners, who were ever clamorous enough to work, drink, and fight among themselves, and buy from and sell to each other until, through mismanagement growing out of their almost constant contentions, the claim failed to be remunerative and they ceased work. The present owners came into possession of the ground called now the Polar Star claim, about eight months ago.

Mr. John S. Colgrove, a member of the company, is the superintendent. Mr. Colgrove has been a resident of this town for the last seventeen years, engaged in hydraulic mining, and is, truly, not only a representative miner with large experience, but a man of extensive and varied general information; he is a careful business man, with more than an average business capacity; he is, above all, a good thinker, with sound judgment. He thinks slowly, but always to a purpose; intensely sanguine, he never admits a possibility of failure; lacking idealism, he is wholly, I may say severely, practical and realistic; he is sufficiently methodical for all business purposes, and lastly, and chief of all his attributes, a thoroughly honest man, "The noblest work of God." I cannot say less of the superintendent of the Polar Star, notwithstanding I have been, by many of my acquaintances, accused of sycophancy because of my published estimate of the ability and character of the superintendent of the Cedar Creek company. I never bow the knee to Mammon, place or pelf, nor indulge in obsequious flattery. I give my estimate of these men for the very reason that the success or failure of any mining enterprise in our deep gravel beds depends largely upon the pilot at the helm, and I confidently advance the opinion that not one out of every hundred of even our old hydraulic miners can successfully conduct one of our mining enterprises of to-day, nor is one in twenty fit for, simply, a foreman; consequently a good superintendent must be a good judge of men as well as measures. We have had enough of dorseyism, dishonesty and defeat, and I am proud to chronicle what I conscientiously believe to be the dawn of successful deep hydraulic mining in this section.

In connection with the Polar Star I will also treat of the

Southern Cross

Hydraulic mining company. Mr. Colgrove is superintendent of both, and the development of each is carried on in a measure jointly. This company owns what was formerly known as the Dutch Flat mining claim, embracing forty and one-fifth acres, adjoining the Polar Star on the west or lower down the channel; it reaches from rim to rim, lies in a compact body and is a valuable piece of property. Mr. Colgrove has been one of the principal owners and workers of this claim for many years while the top bench was being worked off. It is impossible to tell what the Polar Star ground has paid, but we have the account of the Southern Cross, from which has been taken \$155,000, more than one-quarter of which was paid for water alone. This claim has put more clear money into the pockets of its owners in the shape of dividends than any other hydraulic claim in the district. The gravel over the center of the channel is 220 feet deep, while on the Polar Star it will not average along the deep channel portion more than 175 feet.

The Southern Cross is a California incorporation, the members thereof also being stockholders in the Polar Star. Both claims were purchased and incorporated upon at about the same time, and Mr. C. J. I understand, is largely interested in both. Previous to the purchase a contract was entered into between these companies and the South Yuba canal company, by which the latter bound itself to furnish to the former, as long as desired, 3,000 inches of water. They then purchased and contracted with the Gold Run ditch and mining company to run two tunnels—one for each claim—600 feet for the Polar Star and 1,050 feet for the Southern Cross. The latter company, being the owner of a Burleigh drilling machine, which they

work by air compressed by steam power, commenced work on the

Polar Star Tunnel

On the 20th day of last August. This tunnel is already completed, and over four hundred feet of the Southern Cross has already been run; it, too, will be completed, probably as early as the first of next June, possibly before. These tunnels are 9x9 feet on a ten inch grade to every twelve feet, run in the inevitable hard trap stratum of rock which underlies this gravel deposit, as before explained. The months of these tunnels are about 1,200 feet apart, and both debouche into the canon of Bear river, 500 feet above the bed of the stream. The head of the Polar Star tunnel is thirty-four feet below the surface of the rock under the center of the channel, and 209 feet below the surface of the gravel. An incline, now nearly completed, is being raised from the head of the tunnel, at an angle of about fifty degrees, 8x8 feet in dimensions and 150 feet long.

The head of the Southern Cross tunnel, under the center of the channel, will be forty feet below the surface of the rock, and 260 feet below the surface of the gravel. Tail-flumes will be laid, in fact, are now being constructed along down on the side of the canon to the river, provided with a suitable number of under-currents, which are indispensable as gold-savers. These flumes will be five feet wide and paved with blocks. Mr. C. is, as yet, undecided as to fluming the tunnels for a year or two after washing commences. Should he conclude not to, he designs to try the somewhat novel experiment of laying cross ties therein, six or eight feet apart, paving between them with rock, and lay the whole with the heaviest railroad rails, placed about eight inches apart. Should he conclude to lay a flume in the first instance, it will be paved with blocks, and then laid with rails.

Of course, he would not expect to clean up the tunnels until the rails had fulfilled the purpose in view, which may be stated thus: I know of other hydraulic mines in California bearing great masses of large boulders—tough, dense trap boulders, which predominate in the lowest or blue stratum of dirt—as the mines of the Dutch Flat district; in this respect our mines excel. The giant powder consumed at the Yankee claim in the blasting these boulders has cost, on an average, \$50 every twenty-four hours, aggregating \$1,500 every month for powder alone, and this, when we consider the men employed and time expended in blasting and clogging the boulders, the waste on eddies, gads and picks, regardless of the loss arising from the non-use of water while thus engaged, cannot be less than half the actual expense of reducing the rocks. Mr. Colgrove purposes to avoid this expense by the adoption of the above mentioned device until such time as he shall have opened his claim to the bed-rock, and cleared a space for a derrick, and the boulders to be swung back by it, which will, I predict, be at least two years from the time he commences washing. It will require a large amount of water to move the boulders whole than in fragments, but he will have a much better bank of dirt and fine gravel to aid him than he to be had in the Yankee, for in neither the Polar Star nor Southern Cross is any of the barren trap-slide found except upon the eastern side of the channel. The chief difficulty which he will experience in carrying out this plan, will be in forcing his large boulders into the sluice. When once started with the current of water and earth fairly behind them, they are likely to rest in Bear river, but it is my opinion that this cannot be done, except near to the opening of the incline, unless he washes above the bed-rock on a steep up grade as he recedes from the opening; this plan may be followed, for I am convinced that twenty feet of the bottom will pay much better to mill than to hydraulic.

In my next I will give an account of the preparations for hydraulic on these claims. Dutch Flat, Jan. 11th, 1876.

Manufactories of San Francisco.

We take from the *Bulletin* the accompanying interesting tabulated statement concerning the manufactures of San Francisco, giving the details of cost, value of products, capital, wages, men employed, etc.: "A little over three years ago the *Bulletin* published an industrial exhibit, which showed that the manufactures of the city for the previous year equalled \$52,603,475 in value, without taking into account the value of gold and silver refined. The exhibit now published shows the value for 1874 to have been \$67,333,930—a little over twenty-five per cent in excess of that of 1871. The vantage ground gained is satisfactory, as at the rate of twenty-five per cent. every three years the quantity of manufactured goods turned out of our industrial establishments would be doubled every ten years. Indeed, there is no limit to the industrial development of San Francisco. Favorably located and adjacent to countries with teeming populations, with no competitor for their trade nearer than England, Germany or France, its situation and advantages would seem to justify very extravagant dreams of future industrial and commercial empire. Even as it is, and with a trade only in embryo, our far off competitors manage to sell on the coasts of the Pacific manufactured goods annually worth \$150,000,000. So that irrespective of all future developments in Pacific commerce, we have even now a mighty trade to conquer, as our exports of local manufactured goods to all countries last year did not exceed in value \$4,369,250.

"The labor employed in the manufactures of this city represents, with those dependent on

it for support and the trades people patronized, at least one-third of the whole population. The total number of hands employed last year was 24,490, of whom 10,813 were Chinese. Of the rest 9,713 were white men, 2,697 white women and girls, and 1,485 white boys. The wages paid amounted to \$11,251,943, or under \$500 per annum. But it must be remembered that the Chinese, women and boys, aggregating 14,995, or about three-fifths of the whole number employed, hardly average a dollar a day.

The average of the white men employed would be about \$700 per annum, but most of the white labor is unskilled. Skilled artisans earn from \$3 to \$5 per day, and average, taking into account slack periods, \$850 to \$1,000 a year. Some Chinese cigar makers earn \$15 a week, and a few still higher wages, and many white women do quite as well. The number of new industries springing up is rather limited, or rather a great number after being tried for a while are again abandoned."

MANUFACTURES OF SAN FRANCISCO FOR THE YEAR 1875.

SCIENTIFIC PROGRESS.

Cause of the Distance between Flame and Burner.

The fact that a gas flame does not touch the burner, nor the candle flame the wick, was examined by B. Blockman. In a bright luminous flame the contrast of the luminous part is so great as to admit of close observation; but, if the cock is gradually closed, a small space will be seen between flame and burner, which becomes more and more distinct as the flame decreases. This intervening space is considerably increased when the gas is mixed with an indiffereat gas—as nitrogen, carbonic acid, etc. It is thereby possible to increase this intervening space, with a quick gas current issuing from the burner up to two inches and more. Blockman found by experiments that the cause of this rising above the burner was not the result of increased pressure, and inferred that it was a consequence of dilution with indiffereat gas. He explained this phenomena as follows:

After asserting that not only in sounding flames, but in other flames as well, an instantaneous combustion always takes place in the lower part of the flame, which can only be the case when the escaping gas has mixed with exactly the right proportion of air, he finds the increasing distance between the flame and burner, resulting with dilution with indiffereat gases, based on the following:

"The diluted gas on leaving the burner mixes instantly with air. The constancy of the flame requires with this mixture a certain amount of combustible gas. In order not to produce in this case a combustible mixture which contains as much gas as the one which would be produced if undiluted gas escaped from the burner, a much larger volume of gas must leave the burner—i. e., the distance between the burner and flame must be increased."

To this somewhat forced explanation objection is made on account of the following facts: If carbonic acid is somewhat in excess, the flame may be extinguished by the smallest current of air. The more carbonic acid the gas contains the more space will be found between the flame and any cold body introduced therein—for instance the hole made in the flame by the introduction of a cold thick wire. If the amount of carbonic acid is increased to such an extent that the flames will be one inch or more away from a burner tube, say of rolled sheet platinum, placed horizontally, and the tube is then heated near the open end by a Bunsen burner, the flame will approach the burner, and as soon as the platinum tube becomes red hot, the flame will commence at the outer rim of the tube without intervening space, while a non-luminous flame which contains large quantities of indiffereat gas becomes extinct for quite a large space upon the introduction of a cold, thick wire; the opening made in the flame closes gradually as the wire becomes heated. In case the wire is heated previously, there will be no space produced, and the flame will touch the wire all around. In a much diluted flame these phenomena are much more apparent, but even in the common gas flame they are quite distinct.

All these facts force upon us the conclusion that these spaces are produced by heating influences; that the spaces are increased in flames much diluted by indiffereat gases is only a consequence of the already low temperature—which in turn is a consequence of the large volume of gas which takes up the heat of the quantity of gas burned in the unit of time. The flame will join itself to the red hot burner tube even when produced by diluted gases.

It seems, therefore, to be proved beyond doubt, that in all these experiments the intervening space is produced solely by the cooling action of the burner, or by the same action of the cold object introduced into the flame.

The Frog in Science.

St. George Mivart, of London, has recently published an interesting volume on "The Common Frog." The opening of the work is devoted to the consideration of

What is a Frog?

To the casual observer the question may appear susceptible of a ready answer, but a perusal of this work will show that to define a frog accurately many facts have to be taken into consideration, for while the great majority of persons—even with some scientific knowledge—would class it with reptiles, it in reality differs as much from that genus as it does from fishes, mammals, and birds. Very few creatures present so many phenomena as the frog, and it is therefore surprising zoologists have, as a rule, paid so little attention to it; but as Mr. Mivart observes, "The frog is the never-failing resource for the physiological experimenter."

It would take long indeed to tell the sufferings of the much-enduring frog in the cause of science! What frogs can do without their heads; what their legs can do without their bodies; what their arms can do without either head or trunk; what is the effect of the removal of their brains; how they manage without their eyes and without their ears; what effects result from all kinds of local irritation from chokings, from poisonings, from mutilations the most varied? These are the questions again and again addressed to the little animal which,

perhaps more than any other, deserves the title of "the martyr of science." In the course of his investigation into the structure and nature of the frog, the author dissects each portion and contrasts it with other vertebrate animals, and this examination makes known to us an animal of peculiarly specialized and perfect organization. The definition attained is that the frog is a "Tailless, lung-breathing, branchiate vertebrate, with four limbs typically differentiated, undergoing a complete metamorphosis, and provided with teeth along the margins of the upper jaw"—a definition which we venture to say very few persons could have given. A tabular statement is given showing the differences which exist between the frog and the entire class of fishes, reptiles, birds and mammals.

New Alloy for Iron—Soft Steel.

Experiments prove that by using chromic iron instead of spiegel-iron, extremely soft steel is obtained; rods made for experiments were very easily bent, even by hand. It is seen, from these attempts to replace spiegel-iron by chromic iron, that the use of the chrome iron alloys is limited, and the steel obtained is for most purposes too soft for the manufacture of such materials as rails, axles, tires, etc.

During some experiments with the chrome iron alloys, a strange phenomenon was observed. It is well known that chromium is extremely hard, and scratches even hardened steel; meanwhile an alloy was obtained which was malleable, and in a fresh state could be easily bent. It was also remarked that sometimes in opening the crucibles nothing but slag was found; but in breaking the crucibles, the alloy was found to be in the bottom of them. That may be attributed to the corrosive properties of the liquid alloy, which often penetrated even through the bottoms of plumbago crucibles.

The above mentioned alloy was analyzed, and the following average composition was found: Metallic iron, 96.40 per cent.; metallic chromium, 2.30 per cent.; carbon, traces; lime, silica, 1.30; total, 100.00. By melting a mixture of cast iron, tin, and lead in the following proportions, a very liquid alloy is obtained: Cast iron, 79.00 per cent.; tin, 19.50 per cent.; lead, 1.50; total, 100.00.

The alloy has a very handsome appearance, and fills perfectly well the casting molds; thus it could be used for casting small articles. The alloy is to some degree malleable.—*Chemical News.*

THE NEW METAL, GALLIUM, ISOLATED.—Gallium has at last been obtained in a metallic form. On December 6th, M. Wurtz submitted a specimen of it to the Academy of Sciences. It is a beautiful metal, taking rank for luster between platinum and silver. It was obtained by electrolysis of the aqueous solution of its ammoniacal sulphate, the precipitate being submitted to the furnace. M. Lecoq, the discoverer of the new element, has been pursuing his investigations, and finds that it dissolves in hydrochloric acid with disengagement of hydrogen, feebly in the cold and more easily when aided by heat. Gallium having strong affinities with zinc the separation of the two metals is not at all easy. To effect it, M. Lecoq treats the solution of the two metals with carbonate of soda, which precipitates all the gallium and only a little zinc. The precipitate is redissolved in sulphuric acid, and neutralized by an excess of ammonia. Acetic acid being added the whole is boiled. The oxide of gallium is precipitated, behaving in this like the oxide of aluminium. As another analogy with aluminium may be noted the combination of the sulphate of gallium with alkaline sulphates, giving origin to an alum, which crystallizes in cubes.

THE SUN.—At a lecture recently delivered in Glasgow, Scotland, by J. Norman Lockyer, on "Recent Researches into the Chemical Constitution of the Sun," Sir Wm. Thomson, who presided, remarked at the outset, that much of what we knew as to the chemical constitution of the sun was due to Mr. Lockyer's own researches. In the course of his address Mr. Lockyer referred to the metals that were known to have existed in the sun previous to the discovery of the new methods of analysis more recently employed, and the additional metals the presence of which has since been revealed. He pointed out that by means of photography the solar spectra could now be much more easily and accurately compared with the spectra of individual metals, and he also described methods by which not only qualitative but a quantitative analysis of the sun's spectrum could be made. The introduction of photography alone had resulted in eleven new metals being added to the list of solar metals within the last few months.

MAGNET OF IRON FILLINGS.—Jamieson has read before the Academy of Sciences a paper on the production of magnets from fillings of soft iron. These are collected in copper tubes, subjected to pressure, and magnetized in the usual way, a magnetic force being induced which is equal to that of a steel rod of similar dimensions. The case is thus presented that a metal possessing in its whole state no magnetic power, may by division and the compression of its particles into a new body take on as great an inclination for magnetism as steel. The polarity is supposed to depend upon the separation of the particles, and the magnetic property of steel is supposed to be referable to the same principle.

THE NEW TELEGRAPH KEY.—A new key is being put into the telegraph offices of the Pennsylvania railroad. Under the existing system a key and sounder are required for every wire with which an office has connection. The new key can be connected with a dozen or more wires in turn, and requires no separate sounder. The key revolves upon a disc of hard rubber, attached to which, and projecting from its under surface, are a number of platinum points, representing as many connecting wires, to any one of which the key can be turned, and it can be disengaged by a touch. This mode of connection, apart from its convenience, is said by the operators to obviate a difficulty familiar to those using the old key, whose point of contact is in the armature upon which it works, in which the current is frequently weakened or interrupted by the clogging of the points resulting from the constant friction.

A MAGNETIC ISLAND.—The volcanic rocks composing the foundation of the Isle St. Paul are ferruginous. Those on the north side of the crater, which result from the slips whereby all the east side of the mountain is laid bare, attract the two poles of a magnet, and contain 6 per cent. of iron. Those met with around the cones of scoria, situated at the foot of the exterior slopes of the crater, on the sea shore, are true magnets with two poles, containing 14 per cent. of iron. The observations made for declination and inclination indicate the local action of a south pole toward the center of the crater, a fact which should warn navigators to guard against the magnetic influence of this isle.—*Comptes Rendus.*

MECHANICAL PROGRESS.

The Brayton Aero-Gas Engine.

One of the notable features of the last meeting of the Wagner Institute, at Philadelphia, was the exhibition of the so-called Brayton motor and aero-gas engine of quite original construction, which has attracted considerable attention from our engineers. The chief points of novelty of this device will appear from the following description: In construction this engine closely resembles the steam engine; its cylinder and piston, its valve gear and its connections being essentially the same. The principal difference consists in the addition of a compressing pump and a reservoir, for the purpose of compressing and of retaining a quantity of combustible gases, mixed with a proper proportion of air for its complete combustion, and at a pressure exceeding that which is proposed to have exerted in the working cylinder. This reservoir, therefore, stands in the same relation to the engine as does the boiler to the steam engine. A jacket surrounds the cylinder, through which water is kept constantly circulating. The comparatively low temperature thus secured in the walls of the cylinder permits of the adoption of the same construction of piston, with its metallic packing rings, which has become standard in the steam engine. It also permits of the same method of lubrication. A diaphragm, composed of several layers of wire gauze, is placed at the opening, through which the gaseous mixture enters the cylinder. This is of more closely woven material than that used in the safety lamp, as well as of several thicknesses instead of but one, and is an effectual preventive of the ignition of the mass of gas enclosed in the reservoir. A similar diaphragm, but of much smaller area, allows a very small quantity of gas to stream continuously into the cylinder, and as this current is not interrupted by the closing of the induction valve, its little jet burns constantly, and is always ready to ignite an entering charge. Should the gas by any anticipated accident reach the reservoir, the expansion of the confined gas consequent upon its explosion will, it is affirmed, simply open the safety valve, which is given considerable area, and no harm is done. The additional precaution, however, is taken to make the walls of the reservoir very strong. The thorough mixture of air and gas to insure complete combustion is accomplished by taking the illuminating gas and air, in proper proportions, into the compressing pump together, and the mixture here made becomes more intimate in the reservoir, and in its progress towards the place where it does its work. Where a liquid hydro-carbon (crude petroleum, for example) is employed in place of gaseous fuel, as was the case in the engine exhibited at the Institute, the reservoir is filled simply with air, and the carburation takes place at the point of combustion. In this arrangement, it will be observed, the explosive compound is not formed until it arrives at the combustion chamber, a disposition which renders it possible to work with but a very minute quantity of liquid in the apparatus at any one time, while at the same time an explosion in the reservoir is rendered impossible.

QUICK WORK.—The order for seventeen powerful "consolidated engines," requiring twice the work of an ordinary freight engine, was given at the Altoona shops, Pennsylvania railroad, on November 8th, and on Saturday, December 11th, they were all on the road ready for business—a feat in mechanism truly remarkable. The engines each weigh 95,000 pounds.

Steel vs. Iron Rails.

The influence exerted upon the market by the introduction of steel rails is becoming more and more apparent every day. In allusion to this matter the Cincinnati Times says: "The continued depression of the iron market, not only in this country but also in Europe, is a subject for thoughtful consideration. The wonderful growth of the iron production of the world, from 1835 to 1865, marked it emphatically as the iron age; and during that period was built almost our entire system of railroads, covering over 73,000 miles of track, and requiring 7,300,000 tons of railroad iron in its construction. The annual wear and tear, estimated at ten per cent., would require 730,000 tons per annum of railroad iron. Since 1865 Bessemer steel rails have been growing in favor and decreasing in cost, and to-day the Bessemer plants of this country are capable of producing 350,000 tons of steel rail per annum. When it is remembered that each steel rail possesses fully seven times the life of an iron rail, it is to be wondered at that so many of our iron rail mills are churning their production to merchant bars? Every ton of Bessemer steel rails that has been put into the railroads of the country for the past ten years has possessed a wearing life, as compared to iron rails, as seven to one. It requires very little calculation to estimate the required production of steel rails, not only to cover the entire wear and tear of all our roads, but in a few years to replace our iron roads with steel rails. When this is accomplished there will only be required 73,000 tons per annum to supply the wear and tear that in 1865 required 730,000 tons of iron. This will account in part for the decreased production of pig iron in the country for three years past. In 1872 there were produced 2,854,558 tons of pig iron; in 1873, 2,869,278 tons, and in 1874, 2,689,413 tons—a falling off of about 16 per cent. in the production of pig iron in two years. This was fully equalized by the low wear and tear of steel rails that had gone into the railroads since 1865."

Experiments With Iron.

The well known French chemist, M. Gailletel, has continued his researches into the absorption of hydrogen by iron, with some interesting results. It appears that when an iron plate is attacked by sulphuric acid being poured over it, a portion of the hydrogen produced is absorbed by the metal, and the pressure of the gas which is accumulated between two iron plates, welded together, is sufficient to counterbalance a column of mercury thirteen and three-fourth inches high. This singular property of hydrogen, which has also been confirmed, lately, by the investigations of M. Sevois, is regarded by the latter as a most interesting discovery, and he attributes to the presence of carbonic oxide, or hydrogenized gas, the brittleness which some classes of iron manifest when an attempt is made to draw them into wire—a fact well known to workers in this metal.

It is also found that when decomposing by the galvanic battery a solution of chlorate of iron to which sal ammoniac has been added, metallic iron may be collected at the south pole in the form of a brilliant wart, brittle and often hard enough to scratch glass. This iron, after being washed, evolves, either under water or another liquid, numerous bubbles of a gas, which is pure hydrogen. When freely exposed to the air, galvanic iron loses only a portion of its hydrogen; under water, especially water heated to 140 or 150 degrees, the hydrogen is given off with violence. As to the quantity of hydrogen iron thus treated can take up, it seems that, for one volume of iron, the amount is two hundred volumes of gas: in weight, thirteen parts of iron absorb one part of gas. When a lighted match is applied to this iron, saturated with hydrogen, the gas burns like alcohol.

THE BRITISH CHANNEL TUNNEL.—This gigantic enterprise seems to be constantly gaining strength in the minds of both engineers and capitalists. It has recently secured the countenance and assistance of M. Ferdinand Lesseps, to whose persistent energy and undiminished courage the world is indebted for the Suez canal. M. Lesseps has presented a memoir on the projected tunnel to the Academy of Sciences, in which the result of the recent survey is very favorably reviewed. The sinkings at both extremities of the proposed cutting brought to light a dense stratum of chalk at a convenient depth, and the formation had been carefully traced, in an almost methodical course, from the French to within a short distance of the English shore, when further operations were discontinued owing to the severity of the weather. This work will be finished in the beginning of next year; and if, as is confidently expected, no insuperable obstacle presents itself, the horizontal boring will then be commenced. That will offer no difficulty, for infinitely harder rock than the most compact chalk can now be easily pierced, and from the uniformity of the material, the total cost of the work may be the more accurately estimated. The commercial, indeed, is now the only unsolved problem; and it is satisfactory to know that M. Lesseps has no doubt on that point. He is confident that the number of passengers who may be expected to travel annually between Paris and London will reach at least a million, and this number, at only \$2 each fare, would give a yearly income of \$2,000,000 from the profit on passengers' fares alone.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

BALAKLAVA.—*Alpine Chronicle*, Jan. 8: Work on this mine is to commence within a few days. This may be prompted by the United States mining act. Although the owner of this claim says he does not believe any person is so mean enough to relocate the Mountain mine, yet this contemplated move looks as though he is afraid to leave his own property to the cupid of some person who might be just mean enough to accidentally turn up, when least expected, and confiscate it. It makes a great difference whose hill is around about those times.

CALAVERAS.

RICH QUARTZ.—*Calaveras Chronicle*: The Champion mine at West Point, in this county, owned by Messrs. Haskins & Hadley, continues to produce largely. In fact, we have no knowledge of any other mine in the States that produces richer rock than the Champion, neither do we know of one that yields better, considering the comparatively limited scale upon which it is worked. The result of a recent clean-up fully maintains the reputation of the mine. Fifty tons of ore were put under the stamps, producing \$6,000—an average yield of \$120 per ton. And that is not an exceptional production for the Champion. None of the quartz extracted—from the surface down to a depth of 180 feet—has paid less than those figures, while some of it has exceeded them considerably. Notwithstanding the large amount of money that has been taken from the mine it is yet really undeveloped. But little work has been done on the main ledge, nearly all the ore extracted having been taken from a "spur" or "stringer." We understand that operations will soon be commenced on the principal vein, when we look for a large increase in the production of ore and bullion from the Champion.

GWYN MINE.—The work of running the 1100-ft levels in the Gwyn mine has been commenced and is being prosecuted with energy. The mine is now entirely free of water, the pumps working nicely, and no further trouble is apprehended on that account this season. The 1000-ft stopes continue to yield the usual quantity of good ore, and the mills are kept constantly employed. There is an abundance of ore remaining in the 1000-ft stopes to keep the stamps busy while the lower levels are being opened. The mine is now supplied with powerful hoisting and pumping machinery and ample milling facilities, and its prospects were never more flattering than at present.

GLENCOE DISTRICT.—THE GRASSHOPPER MINE.—The company recently incorporated as the Grasshopper mining company are now reopening this valuable mine, which has been lying idle for several years. It is situated in the western end of the village of Mosquito. Adequate steam hoisting works were recently put up over the old main shaft, which is not quite 100 feet in depth. The mine is well known for the extraordinary uniform richness of its ore, which exceeded even that of the Champion in the West Point district. The rock is of a dull white color, yielding magnificent specimens at times. The trend of the vein is north and south, conforming with that of the country rock (slate) on the west side. East of the fissure, and extending east about two miles, to within a short distance of the Poorman mine, the country rock appears to be slightly tilted, and the numerous valuable veins in the area of the apparent dislocation trend in an east and west direction, deviating probably twenty degrees from the trend of the country rock.

The Rickman mine, which is enriching its owners, is a strong east and west vein. Its works are 200 yards east of those of the Grasshopper. Glencoe district has furnished a generous quota of amalgam ever since we can remember, which has been rapidly increased within the past year. But little low grade ore (rock milling less than \$15 per ton) has been worked so far, on account of the meagre milling facilities. If the companies who have recently acquired possession of several of the best mines of Glencoe district have sufficient pluck to carry their properties through the proper primary stages of systematical development, the district will easily double its gold product this year.

INYO.

COSO CONSOLIDATED.—*Coso Mining News*, Jan. 14: Work in the Bella Union mine—one of this company's—is being driven ahead as fast as possible. The drift on the lower level is being pushed steadily along, and as yet there is no diminution of the ore, in fact the mine is daily improving, and the developments are such as to prove that our mines are truly wonderful in breadth and richness of ore. The Coso Consolidated company commenced hauling ore from the Bella Union mine on Tuesday last, to their furnace, and as they have a good supply of coal on hand, they will soon commence the shipment of bullion.

DEFIANCE FURNACE.—This furnace is running as well as any furnace ever did, and as well as is necessary for the speedy and rapid reduction of ore and the manufacture of bullion. It has not ceased for a moment since our last report, nor met with the least accident.

Under the superintendency of P. Reddy, Esq., the mine and furnace property of this company is being developed in a most rapid and wonderful degree.

NEW COSO MINES.—The works at the mines of this company are pushed with great energy and vigor. In our last visit to the Christmas Gift and Lucky Jim we were astonished to find quite a little town. Every day improvements of all kinds are taking place. The company has lately built a large and comfortable boarding house for the comfort of their employees—also an office for the foreman, where are kept a plan and drawing of all the workings of the mines—powder magazine and storehouse.

KERN.

MINING INTERESTS.—*Cor. Southern Californian*, Jan. 14: Havilah in the last year has not come up to the expectations of many of the speculators who were expecting another period of excitement, where every stratum and barren quartz ledge was sold for a mine, others who have been quietly working their ledges are quite satisfied with the result. We still have two country stores and the same number of hotels that cannot be excelled this side of the bay, all of which are doing a good business. The tardiness of San Francisco capitalists to invest here can only be accounted for in the failure of former companies, who crippled themselves by paying enormous sums for the privilege of demonstrating whether they had purchased a mine or not. The mines of Kern, like her rich lands, will not always be overlooked; all the practical miners that have visited Havilah in the last year agree in saying that in no part of the State can richer or more accessible mines be found; freight at any time of the year will not exceed two cents per pound from San Francisco to the mouth of the mine; a healthy and moderate climate, wholesome water and timber in abundance; labor as cheap as in any part of the mines—in fact, nothing seems to be needed but a little money and a good deal of energy. We have proved this in the last five years, in every instance where parties have done a reasonable amount of work they have been well paid.

MARIPOSA.

COUNTY MINING ITEMS.—*Cor. Tuolumne Independent*, Jan. 7: The old French mill, on the creek below the village of Coulterville, with its 50 stamps, is and has been pounding rich rock from the mine on Black creek. This is the Ralph Jones mine, or the one that gentlemen sold to the company some time ago for the sum of \$10,000, as I learn from some of his neighbors. There are a large number of rich lodes in this section of country. The Banderita mine, on the north fork of the Merced river, is paying handsomely. This is the old Goodwin mine, and has been worked profitably about 20 years. Operations on the following mines, in the vicinity of Gentry's gulch, are suspended until spring: These are the Coward mine, the Walden mine, and some others of lesser note. Mr. Sculan, at the junction of Gentry's with the north fork, is grinding very rich rock by the arrastra process. He tells me that he intends to put up one of the latest improved mills. In spring, things will be in readiness about these mines, and the different companies will commence to develop them at an early day; so times promise to be lively in this neighborhood in 1876. There is also some talk of opening the Marble spring mine, near Bull creek; the rock crushed from this mine was very rich, but it is a very expensive mine to work, the water in it being very troublesome, and the difficulty of tunneling through the hard rock to drain it is very great; but I believe that it will be a fortune to the owners when thoroughly opened. There are also other mines in that vicinity that will pay largely when properly managed, and the Skunk Gulch mine is one of them. The last named mine is owned by John A. Hite, owner of the celebrated mine at Hite's cove. Quartz mining is the chief industry of Mariposa county, and yet it is not half as rich in mineral wealth as Tuolumne and Calaveras counties. But quartz mining is followed with greater vigor in the former than in the latter named counties; and the only reason I can give is, that placer mining in Tuolumne and Calaveras counties paid better than in Mariposa in days gone by; consequently the miner turned his attention to quartz mining at an earlier date here than in the other two counties. The fact is, quartz mining in Tuolumne is only a sucking baby—that is all.

PLACER.

CLEANED UP.—*Placer Herald*, Jan. 15: The Auburn gravel mine made its third clean-up last Saturday. We have been unable to obtain particulars regarding the result, but from what information we have, it seems the yield this time, in proportion, was even better than previously. This is accounted for by their present proximity to what, in hydraulic mines, is known as the channel, by which is understood the greatest depression in the bed-rock, the miner invariably expects to find it the best pay. This mine, it is not supposed, will prove an exception, and therefore we may reasonably expect to continue to hear of favorable returns.

GOOD FRIDAY.—A sample rock lies before us from the Good Friday mine, located a few miles west of Auburn, which shows free gold profusely. The developments of this mine, which is now under the superintendency of J. M. Bryan, are very encouraging. The main shaft is down we learn one hundred and sixty feet, as deep as the present machinery will admit. The ledge is from eighteen to twenty-four inches thick, and the rock yields well, the last crushing of eight tons turning out \$1,080.

Such results indicate that the Good Friday, which heretofore has attracted but little notice, will soon rival the famous Crater.

TUOLUMNE.

MINING ITEMS.—*Tuolumne Independent*, Jan. 18: The Riverside mine has started up again. The Soulsby mine cleaned up over nine thousand dollars for the last month's run. John Conlin, on Experimental hill, near Columbia, has struck an exceedingly rich vein of quartz about four feet wide; down in the gulch they have struck the same vein at a depth of eighty feet. The gold sticks out of the quartz in every piece in big chunks. It is the richest ore we have seen. Some of the quartz is crystallized and the gold is massed in the crystals. He has taken S. W. Pitts as partner, and they intend to haul some of it to Thurman's mill to test its average yield.

Nevada.

WASHOE DISTRICT.

BULLION.—*Gold Hill News*, Jan. 13: Sinking the main incline is progressing finely at the rate of five feet per day. The upraise from the 1,700 ft level to connect with the bottom of the incline is ascending at the rate of from five to six feet per day. The Burleigh drills in use in this raise are doing splendid work. The northeast combination drift on the 200-ft level is steadily advancing, the rock in the face gradually softening and showing streaks of quartz, indicating a nearer approach to the main ledge.

KOSUTH.—A drift west from the bottom of the winze at the 300-ft level is in a distance of thirty-eight feet, the face in a fine quality of white quartz, very much resembling the ores of the Consolidated Virginia and Ophir. This quartz affords excellent assays, mostly in silver, and the indications of a paying body of ore are daily growing more encouraging.

NEW YORK CONSOLIDATED.—Raising up on the third compartment of the shaft is making excellent headway. The prospect of finding pay ore on the 800-ft level is growing better, and giving great encouragement to the stockholders. It is confidently believed that the development of another rich body of ore to the east of the Belcher and Overman is only a matter of time; and if so, the New York will certainly be one of the first mines to find it.

BELOREA.—Daily yield 450 tons of ore. The ore breasts and stopes show but little, if any change during the week, the ore continuing of a good character, and being shipped to the mills for reduction as fast as it is extracted. The water is nearly drained from the 1600-ft level, ready to again resume work in that portion of the mine. The air shaft is completed down to the 1500-ft level.

JULIA CONSOLIDATED.—The main south drift on the 1400-ft level is being advanced five feet per day, the ore prospects in the face gradually increasing as the drift enters the ledge.

CONSOLIDATED VIRGINIA.—Daily yield 600 tons of ore, keeping the mills all running up to their full crushing capacity. The ore breasts are all looking well and yielding rich ores as usual. The crushing capacity of the mills will be increased in a few days, which will add over \$800,000 a month to the yield of the mine, or \$2,500,000 per month.

LADY BAYAN.—A fine ore prospect has been developed by the north drift on the 380-ft level. This discovery is in entirely new ground, and is a very important one. Some assays of the ore run as high as \$300 to \$780 per ton, mostly silver. The extent of this ore body is not yet known, but promises to exceed by far anything yet found in the mine. The winze being sunk below the 250-ft level, to connect with the south drift on the 380-ft level, is also showing some fine ore. The course of the ore vein going south is gradually verging more to the westward, and, in the opinion of some, will eventually assume almost the east and west course of the Cannan, and may yet prove itself a branch of the Comstock. Sinking the main shaft is going steadily forward, the bottom in fine quartz, with rich ore coming in on the north, the ore being very similar to that found on the 380-ft level above.

OPHIR.—The water is all drained from the bottom of the main shaft, and the sump is being cleared out and the timbers repaired. The drifts and other stopes have all been re-timbered and put in good working order down to within 30 feet of the 1600-ft level.

CALIFORNIA.—The main north drift on the 1550-ft level is steadily advancing toward the south line of the Ophir, the entire length of the drift being in fine ore. The face of this drift continuing in rich ore is adding vastly to the already known wealth of this famous mine. No other prospecting is being done on the lower levels at present. The California mill has been tried sufficiently to find that everything in connection with the structure works with the utmost perfection. The batteries are being "puddled" with ore previous to setting the whole in motion, and it is expected that the mill will be ready to commence crushing regularly in four or five days more. Sinking the C. & C. shaft is making splendid progress, the rock in the bottom blasting out finely and the work being pushed ahead with all the energy possible. It is now down 995 feet.

LEE.—This mine is situated in the easterly portion of the great Comstock belt, adjoining the famous Lady Washington mine on the north. It is one of the old locations which, after some time spent in securing its title and getting into the hands of men of capital and mining energy, is now in process of good, square, practical development. Excellent and effective work is being done.

MINT.—Sinking the main shaft is making excellent headway, the bottom in good working ground. It is now down 995 feet, and by Saturday will have attained a depth of 1,000 feet. When that point is reached it is the intention to suspend the sinking for a few days, in order to put in ladders and stations, reaching from the bottom to within about thirty feet of the surface, in order to make a way of escape from the shaft for the men in case of fire or other accident. Thirty feet below the mouth of the shaft a tunnel will connect with the ladder-way, so that even should the hoisting works burn down the safety of the men in the mine would still be secured.

NORTH CONSOLIDATED VIRGINIA.—Sinking the shaft below the 630-ft level, to make room for a pump before putting out for a station, is making excellent progress. The bottom of the shaft is showing an increase of quartz feeders. The feeders or stringers all have a strong dip to the east, indicating that the principal ore vein lies in that direction.

AMAZON AND GLASGOW.—The joint shaft of these mines has been sunk to depth of 429 feet below the croppings, during which time two levels have been opened ready for a thorough exploration of the ledge at each point. The third level is now opened, and a cross drift has been started to cross-out and prospect the ore vein.

GLOBE CONSOLIDATED.—A new and valuable discovery of fine ore has been made in a cross-cut west of the old incline in the upper works. This body of ore assays high in silver, being different in that respect from any that has yet been developed in the mine. The extent of the find cannot yet be known, but there is every indication of a good sized ore body being developed.

UTAH.—The new pumping and hoisting machinery will be ready to start up in about two weeks' time.

BEST AND BELCHER.—The retimbering of the Gould & Curry shaft still prevents the extraction of the water from the 1700-foot level, and the resumption of work in that portion of the mine.

GOULD & CURRY.—No work can be done in any portion of the mine until the shaft is completed and the water extracted.

SULLIVAN.—South drift at the adit level in 49 ft from the shaft station. Material the same live, true fissure Comstock ledge matter heretofore mentioned, heavy with sulphurets. Some small streaks of this assay very richly and indicate very conclusively what will be found at a lower level, or even what may be met with at the present level by the same drift.

ORIGINAL GOLD HILL.—Bad roads have somewhat interfered with the hauling and milling of the ore during the week, but not the production from the mine, 20 tons per day being the yield from the main south ore body. The stopes and breasts hold out well, and a raise is being made above the main tunnel level, in the north portion of the ore body, to ascertain its extent in that direction.

CROWN POINT.—Daily yield, 425 tons of ore. This ore is taken from the old ore stopes, and is of low grade, in fact, but little more than pays the expenses of mining and milling.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline has been resumed and is making excellent progress, the bottom in good working ground. The water tank at the 1050-ft station is completed, and the heavy pumps are being lowered into position ready for use when needed.

SERRA NEVADA.—Sinking the new shaft is making steady and favorable progress. The west drift at the 1250-ft station is being pushed rapidly forward to cut and prospect the ore vein.

YELLOW JACKET.—The timbering of the connecting drift between the north and south winzes on the 1940-ft level has not yet been completed. A cross-cut has been started from the bottom of this winze to cut and prospect the ore vein.

PROSPECT.—Streaks of fine looking quartz and clay are being passed through, and the diamond drill is doing very satisfactory work. The main tunnel of the upper workings is driving ahead lively, and at present is passing through streaks of ore which give high assays, over one-third of which is gold.

SOUTH COMSTOCK.—Cross-cut 327 ft in length to-day. During the week a horse of very hard porphyry has been passed through, and the face is now in clay, quartz and soft ledge porphyry of a very favorable nature. The hard as well as the soft streaks have a well defined and decided dip to the east in accordance with the regular Comstock formation.

EUROPA.—The east wall of the ledge has been reached by the west drift on the 320-ft level, and two drifts, one north and the other south, have been started along the east wall of the ledge so as to open a considerable length of the vein before cross-cutting.

LEO.—The south drift is now in 72 ft. A cross-cut has been started from this drift to the east, the face of which is also in ore of a fine character.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. The ore breasts are looking well and the prospects are good for a fair yield for some time to come. The ore indications on the 2000-ft level are steadily on the increase.

JUSTICE.—The stopes and breasts of the 600 and 400-ft levels continue their good ore yield and showing, and good progress is made with the drift south of the 800-ft level, the face being in very favorable vein matter, giving low assays.

OVERMAN.—The main south drift on the 1100-ft level is steadily advancing with more and more favorable ore indications.

LAST month 2,088,329 pounds of hullion, and 2,472,458 pounds of silver ore were shipped over the Utah Southern railroad.

USEFUL INFORMATION.

The Formation of Habits.

We are all familiar with the process. A movement, or series of movements, at first painfully difficult and requiring the whole thought and attention, by repetition become so easy and semi-automatic that attention is no longer necessary. The most remarkable examples of these, such as walking, speaking and the like, probably belong partly to the third category; the capacity for these is partly inherited. Playing on a musical instrument is therefore a better example. We all know the painful attention necessary at first, and the ease and rapidity of the most complex movements attained by practice. Now, by what means, anatomical or physiological, do these at first difficult movements become, by repetition, easy? The answer in general terms, seems to be this: Every volitional act is attended with a change in the brain, which, however slight, is liable to be affected by subsequent changes, and therefore evanescent. If the same act, however, be repeated many times, the change becomes deep and permanent—becomes petrified in brain-structure, whatever be its character or its seat, determines the appropriate acts with precision. It is as if every volitional act produced a faint line, liable to be erased, on the tablets of the brain; by running over the same lines many times these are deepened into grooves and finally into ruts, and motion in these becomes easy and certain, because the ruts guide the motion instead of the will. The repetition produces structure and structure determines habit.

SMOKE PREVENTER.—A new fuel-saver and smoke preventer, us it is called, was first shown in public in Cincinnati the other day. The principle on which it acts is as follows: A current of air is forced by means of either a syphon or a fan through distributing pipes, three in number. The first of these pipes is located in front and under the grate bars, thus forcing the air through the grate. The second pipe is placed above the fire-door, blowing the air into the fire. The third is on the bridge wall, blowing the air forward. The three pipes combined entirely prevent the formation of smoke. It is claimed for this invention that it can be successfully applied to steamships, steamboats, locomotives and even to stoves.

LEAVES of the pine-apple, now being extensively cultivated in the East Indies, are turned to account by being converted into a kind of wadding, which is used for upholstering instead of hair. A sort of flannel is also manufactured from them, from which substantial waistcoats and skirts can be made.

WHAT are they adulterating coffee with now? While Mr. Naugle, of New York, was heating some the other day it exploded, scalding his entire countenance.

Important Postal Decision.

Many merchants in various cities of the country having been in the habit of sending out papers devoted to special interests, in their own name, printed boldly on the wrapper, addressed "in the care of" their customers, at the regular pound rate chargeable on daily papers, the question was submitted to the Postoffice Department, and the following decision has just been rendered:

"That a newspaper or periodical sent by mail to a regular subscriber implies not only the name of the subscriber, but his residence or place of business also. When a subscriber is temporarily absent there would be no objection to sending his paper at the pound rate to the place where he may be temporarily sojourning, but when papers are addressed to subscribers at places where they have no permanent or temporary residence or place of business, with an evident intention to defraud the government of the legitimate rate of postage to which such papers are subject, they should not be delivered until postage has been paid thereon at transient rates, notwithstanding they may be sent to the care of some other individual."

To soften hard gold pass chlorine gas through the molten gold, by which treatment most of the gold which had otherwise to be set aside as unfit for certain kinds of work, can be redeemed.

GOOD HEALTH.

Frost Bite.

Exposure to the cold, of severe degree, often leaves the fingers and toes, nose, ears and lips, more or less frozen. This condition, short of absolute death of the part, is termed frost bite. It will be observed that the portions of the body just enumerated are those most exposed, in area, to the influence of the cold, and are furthest situated from the heart; and it will, perhaps, be unnecessary to remark that persons who are debilitated are more apt to suffer with the same amount of exposure than the robust.

When the circulation of any part begins to succumb to the influence of the cold, it becomes puffy, blueish and smarting. This is because the blood moves more slowly than natural through the vessels exposed near the surface. Soon this blueness disappears, and the part becomes pallid, as if the influence of the cold had contracted the vessels to an extent incompatible with the passage of blood through them. The pain at this point ceases; indeed, until he meets a friend, his friend does not know of his mishap. At this stage the injury has become so great that, unless proper means are taken to restore circulation, complete death of the part ensues, and in due time sloughs away, and is detached from the line of living tissue.

What takes place in a part of the body, known as frost bite, may take place in the whole of it, which is known as "frozen to death." The

blood of the extremities being gradually forced from them, under the continued subjection of the cold, is forced inward upon the larger blood vessels, heart, lungs and brain. There is increased difficulty in breathing, owing to the engorged state of the chest, and, what should always be remembered by one so exposed to cold, an unconquerable desire to sleep. To sleep *then* is to die. If the person exhibits such a symptom, he must, by all means, be kept constantly moving.

Treatment.

Persons exposed like those just described must be treated promptly, and with one thing never lost sight of. That is, keep the frozen person away from the heat. A person taken up insensible, or approaching it, from exposure to the cold, should be taken into a cold room, his clothing removed, and thoroughly rubbed with snow, or clothes wrung out with ice water. The friction to every part of the body, particularly the extremities, must be continued for some time, until signs of returning animation appear. When the frozen limbs show signs of life, the person should be carefully dried; put in a cold bed in a cold room; artificial respiration used until the natural is established; then brandy given, also ginger tea and beef tea. Usually, by this time medical advice will have been secured to direct further treatment. should it not, do not forget that the patient is to be brought by degrees into rather warmer air; and lest in some part there might still be defective circulation, the person should be kept away from exposure to the heat of the fire.

Milder degrees of the same condition, as suspension of life in the ear, nose, finger, or toe from exposure to cold, must be treated with the same general directions in view. The part should be kept away from the heat and rubbed with a handful of snow, or towels dipped in cold water, until circulation appears re-established. Exposure of the part to the heat before, we may say, it has been almost rebuilt, is apt to be followed by sloughing.—*Accidents and Emergencies.*

CONSUMPTION.—The incurable character commonly attributed to pulmonary diseases is seriously questioned by M. Pietra Santa, the malady being, in his opinion, essentially general and constitutional—an alteration of the functions of nutrition, and a disease of the blood; und that, while there is no panacea for the affection, he thinks that many cases may be greatly alleviated, and, indeed, entirely cured by following a rational treatment. Thus, in all periods of the disease, the assistance is to be invoked of suitable hygienic and moral treatment, a pure atmosphere, a tonic diet, moderate exercise and the use of milk for food; the administration of certain mineral waters; a sanitary change of place and migration, always into southern temperate regions during winter, and to mountainous countries in the summer; the use of hyposulphites and the alkaline sulphites for the treatment of the tuberculous matter developed in the lungs; and calling into play the various agencies of therapeutics when they can be made available in the different periods of the disease.

DOMESTIC ECONOMY.

Remarks on Eating.

Professor Blot used to say it is a fact beyond all question that the intellectual and moral faculties of man are influenced in a large degree in their operations by those physical conditions which are dependent upon our food. Physiology proves that it is the contraction of muscles that produces wrinkles; and a person whose food is properly prepared appears younger and more beautiful than one who follows no scientific principles in his eating. Good food, properly prepared, will keep his muscles in order and elastic. Any one, male or female, young or old, starting with a good stomach, can keep healthy and in good flesh with proper food; it is only necessary to select the kind required by the constitution, and prepare it judiciously. It is not what we eat that makes us fat, but what we digest. Bad food may bring a temporary bloatedness, but not the plumpness of good health. He agreed with the opinion expressed by Thomas Jefferson, as well as by a celebrated New York clergyman, that good things have been made by the Creator for good people.

Another thing in food—it ought always to be prepared according to the age of the person for whom it is intended, and for the sex, as well as according to the climate and the season. In winter more fatty matter is necessary to be eaten than at any other time of the year. In spring, greens, which purify the blood and remove the bile occasioned by eating fatty substances in the winter. In winter we need more bile; in the spring we must get rid of it if we would be healthy. When warm or hot weather comes, we must supply the wasted system by eating meat. Meat is better in summer than anything else. It is a great mistake to suppose that vegetables are the best for this season of the year. He recommends roast beef for summer. Skim off the fat. Don't bring fat to the table.

The Borgias of our Kitchens.

Oh, woman! heaven's last, best gift to the kitchen, must you and your daughters still continue to marshal families the salarutns way to dyspepsia? Can you never learn that the grid-iron and the clear, glowing beds of coal, whereupon St. Lawrence himself would have deemed it a luxury to be broiled, better benefit the lordly steak unmacerated with the brutal pestle, uncontaminated with factory lard, and will sooner woo it to turn to pale pink, delicate amber and tender brown (with a sensitive elevation at the corners, forming a central chalice for the reception and preservation of its own juices) than the frying pan, accursed of God and abhorred of men? Know you not that by thinly slicing potatoes—*not* left over from yesterday's noon-day dinner—into cold water, wiping the same dry in a towel, dusting them with pepper and salt, frying them in boiling lard, and as soon as they put on the rich golden brown hue of a Cuban helle, removing and draining them, you can compass that which, at Saratogs, has brought fame and fortune to the artistic restaurateur? Is it not in you to pour boiling water on your coffee, and set the pot over a shovelful of embers in the hearth-box, where it will just simmer and not boil? Can your finer female sense not apprehend the difference between fanning a smokeless fire with a generous slice of bread till the surface of the latter turns delicately golden, then brushing the same with fresh butter, and burning bread on the top of a dirty stove, then swabbing it in melted, rancid oleomargarine? Alas! if experience can be relied on, woe, not. Priscilla is joined to her salarutns and frying pan; let her alone.—*The World.*

WHITEWASH FOR KITCHEN WALLS.—The first consideration in a cooking room is cleanness. Tried by this test, papered walls are an abomination in such a place. You cannot darken this room through part of the day in summer, as you do others, and consequently fly specks will be numerous. These walls absorb the kitchen odors and steam, and the smoke rests lovingly upon them. If creeping things get into a house they are sure to insinuate themselves into the paper on the walls. Hard-finished walls are really more cleanly, for they can be washed; but, unless the finishing is better done than in the kitchens we have seen, they soon look dirty, and this is the next worst thing to being so; for such finishing soon becomes discolored and "splochy." There is nothing that will compare with the old fashioned whitewash; not color wash, but whitewash, pure and simple. The color wash may give the walls a prettier tint, but it must be put on by a practical hand, whereas whitewash can be applied by any one, whenever a dirty spot makes its appearance. It is true that unpracticed hands do not apply the brush as evenly as could be wished, but a few streaks more or less don't matter, when we can all see that the streaks are white and clean.—*Scribner*.

POTATOES should always be put into boiling water to cook, boil quickly and pour off the water, letting them dry a few minutes over the fire before dishing up. Steaming is the best manner of cooking them.

INDIAN GIDDLES.—Two cups of meal, one of flour, one of milk, one of water, one egg well beaten, two teaspoonfuls of cream yeast, sifted into the meal and flour. Mix and bake on hot griddles.

MINING SCIENTIFIC PRESS

W. B. EWER, SENIOR EDITOR.

DEWEY & CO., Publishers.

One inch.....1.50 4.00 12.00 40.00

Large advertisements at favorable rates. Special or
reading notices, legal advertisements, notices appearing
in extraordinary type or in particular parts of the paper
inserted at special rates.

Subscriptions payable in advance.—For one year, \$4;
six months, \$2.25; three months, \$1.25. Remittances
by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in
their renewals to the Press promptly as regularly as
the year comes round. It saves us much expense in
communications for collections and renewals. May we not
request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this
paper to persons who we believe would be benefited
by subscribing to it, or willing to assist us in extend-
ing its circulation. We call the attention of such to
our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set
in solid type, giving in our columns one-third more
reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Jan. 22, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Notices of Recent
Patents; The Fryer Process; California Academy of
Sciences; Charles F. Secor's Return; Coral Islands,
49. Mining Interests in 1875, 56-57.

ILLUSTRATIONS.—Twenty-eight Inch Swing
Lath, Twelve Feet, 49.
CORRESPONDENCE.—Hydraulic Gold Mining
in California, 50.

SCIENTIFIC PROGRESS.—Cause of the Dis-
tance between Flame and Burier; The Frog in Sci-
ence; New Allow for Iron—Soft Steel; The New
Metal, Gallium, Isolated; The Sun; Magnet of Iron
Fillings; The New Telegraph Key; A Magnet
Island, 51.

MECHANICAL PROGRESS.—The Brayton
Aero-Gas Engine; Quick Work; Steel vs. Iron Rails;
Experiments with Iron; The British Channel Tunnel,
51.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notice of Assessments;
Meetings and Dividends; Review of the Stock Mar-
ket for the Week, 52.

MINING SUMMARY from various counties in
California, Nevada and Montana, 52-53.

USEFUL INFORMATION.—The Formation of
Habitats; Smoke Preventer; Important Postal De-
cision, 55.

GOOD HEALTH.—Frost Bite; Consumption, 55.
DOMESTIC ECONOMY.—Remarks on Eating;
The Borgia of our Kitchen; Whitewash for Kitchen
Walls; Indian Grids, 55.

MISCELLANEOUS.—Manufacturers of San Fran-
cisco, 50. Mining Stocks; Dugway District, 54-55.

leroy, Oakland, Cal.

HOUSEHOLD ELEGANCIES.—We have received
from Roman & Co. a useful little work on
"Household Elegancies," containing sug-
gestions in household art and tasteful home de-
corating, by Mrs. C. S. Jones, and Henry T.
Williams. It is profusely illustrated, and treats
in detail of the following subjects, assisting
the description with engravings: Transparenc-
ies for windows, lamps, balls, etc.; fancy
work with leaves, flowers, grasses, mosses, etc.;
spray work or spatter work; brackets, shelves
and mantels; picture frames; fancy letter
work; wall pockets; work boxes and baskets;
wax flowers, fruit, etc.; Indian painting in imi-
tation of ebony and ivory; cone, shell and
seed work; miscellaneous fancy work. This
little book will no doubt be thoroughly appre-
ciated by those ladies who delight in increasing
the beauties and attractions of home by de-
corating it with tasty devices of their own
handiwork.

P. W. JOHNSON & Co. have shipped from
Winemucca to Philadelphia, for the Centen-
nial, eleven boxes of ore specimens, weighing
1,117 pounds, from which it appears that others
beside the State Centennial Commission are
collecting minerals for the big show.

SENATOR JONES' Kernville mine is likely to
prove a second Comstock. An immense ledge
of ore easily assaying \$300 to the ton has been
discovered, and a body of ore which has been
estimated at 600,000 tons has been discovered.

THE Caribou mine at Central City, Colorado,
produced \$204,703 worth of silver bullion last
year, and is expected to do better the coming
season under increased development.

RICH copper deposits have been recently dis-
covered in the Walker river section, about forty
miles south and east of Virginia City. Nearly
\$50,000 worth of ore has been taken out.

It is reported that a rich vein of coal has
been struck near Santa Monica.

Mining Interests in 1875.

As we have kept a faithful record of every-
thing of interest pertaining to mining matters
for the past year, we do not consider it neces-
sary to go into details again at this time in a
lengthy mining review, but will briefly sum-
marize a few facts which bear on the result of
this year's work. We have increased the bullion
product in 1875 over that of any previous year.
The total yield in 1874 was \$74,401,055. This
year it was \$80,889,037.

Of course the great event of the year has
been the unprecedented yield of the famous
Comstock. Last year at this time every one
was excited on the subject of
mining, the wonderful developments on the
Comstock aiding in this and promising a
brilliant yield. Of course the estimates made
at this time were laughed at by many, but the
shrewd ones who placed faith in the calcula-
tions of the mining experts, and had the means
to invest on their recommendation have reaped
and are reaping their rewards.

Probably the greatest advantage of these dis-
coveries, aside, of course, from this wonderful
product of bullion, has been that they have
turned the attention of so many to the mining
interests of the country. Very often do we
hear the remark that "the mines have given
out," and that mining is more of a speculation
than an investment. Whenever stocks are
down the praises of agriculture are sung, and
the "honest miner" is laughed at as a vision-
ary and a thing only of to-day. Already are
some of the farmers in the interior thinking
that they will be able to stop the hydraulic
miners above them from working the mines,
alleging that the tailings are destroying their
farms and that the farms are the more valuable.
The miners, however, have priority of posses-
sion, common custom and common sense on
their side, and the question is one which a
single legislature will not be able to deal with.
Many people consider that the business of min-
ing is merely one of speculation and should
not meet with encouragement. The practices
of some few unscrupulous men have cre-
ated a distrust of mining enterprises among a
certain class of people who look upon the busi-
ness as being closely allied to horse racing or
gambling. They look with deference on the
"honest kings" who have made such im-
mense fortunes by their mining transactions,
but consider it altogether a piece of luck, for-
getting or ignoring the fact that it took
both pluck and money to develop the riches
which nature had placed in the ground for
whosoever would work for it.

Mining is by no means "played out," and
this year has given it such an impetus as it has
not had for a long time. True, the product of
California fell off last year, but the water sea-
son was a poor one. This year promises better
things, and if the Fryer process does halt which
it is hoped to, next year will see many a quartz
claim in this State which is now idle, turning
out the golden ingots to the markets of the
world. No man can look at the figures of pro-
duction and dividend, given herewith, and say
that an industry which produces so much is
not worthy of encouragement.

The argument of "extra hazardous," applied
to mining as a business, does not on investiga-
tion prove true. Other branches of business
make as many failures, but these are considered
to be in the ordinary course of trade. The
fallacy of this reasoning can be shown by an
extract from Dun & Co.'s commercial report,
which says: "The extent of business failures
in the United States, for the past three years
and nine months, was \$635,966,000 divided
among 20,000 manufacturers, shippers, mer-
chants, bankers, etc." Commenting on this,
a contemporary says:

"Now, let us consider the mining business
of our country. It is safe to assert that from
outside sources there was not during that time
exceeding \$20,000,000 invested in mines and
mining enterprises—possibly not more than
half that amount. Let us allow a liberal
margin for any and all losses sustained by im-
prudent investments in worthless mines and
machinery, or mismanagement, and state the
amount at \$5,000,000. Now, what has been
the result? From reliable data from the United
States government, we find that the product
of American mines has for years past varied
from \$60,000,000 to \$70,000,000 annually, and
for the present year it will probably be about
\$100,000,000. Let us take the same period in
which the failures are given, and for the three
years say our production was \$65,000,000 per
annum, and for nine months in the same ratio,
and we have the enormous total of \$260,000,-
000 of created wealth; deduct from this the
\$20,000,000 invested, which includes losses
mentioned, and it leaves \$240,000,000 as an
actual net product.

"Now, while the actual creation of this
amount has made many rich, yet this is a small
part of their wealth. We have yet to consider
their mining estates, which are of such mag-
nitude that any attempt to estimate their value
would be futile. If we say those are worth
thousands of millions, we can only conjecture
how many. The annual incomes of some indi-
vidual members of companies in San Francisco
range from \$5,000 to \$10,000,000. These
stand related to properties that have been fairly
developed, although they yield but low grades
of ore.

"We think there is no question but that

mining, properly conducted, is one of the snarest
ventures that can be engaged in. True, there
have been failures, but generally on account of
want of foresight, from mismanagement and
investing in worthless mines."

It must be remembered, moreover, that the
miners are necessarily producers, and as such
aid our trades and manufactures; they are as
great producers as the farmers, and much
greater in proportion to their number. When
one class of men in a few States and Territo-
ries can produce in a year a sum of nearly
eighty-one millions of dollars out of the ground
itself, they surely ought to receive every en-
couragement possible to renewed exertions.
We talk a great deal about the immense wealth
product of California, and its importance to
the State and nation. Of course every one will
acknowledge the importance of that, but many
deny that mining is of half the consequence.
In 1875 the value of the wheat produced in this
State was \$26,000,000, and the gold pro-
duction was \$17,753,151. When we con-
sider that without doubt there are five farmers
to one miner, the production per capita is
greatly in favor of the miner. Moreover, this
bullion product is only that passing through
the hands of Wells, Fargo & Co., while the
wheat was all carefully considered by the cus-
tomers house officials, flour mills and wheat
brokers.

In one thing, however, mining has now de-
cidedly the advantage, and one which it will
keep. It has capital on its side. Comparatively
little capital in large amounts goes into
agricultural pursuits, but this year has opened
the eyes of capitalists to the advantage of large
returns for investments in mining properties,
and capital no longer treads a desert. On our
big mines big works are the rule, and where
we used to erect ten stamp mills we now put
them up with sixty and eighty stamps. The
developments made in depth in many of
the mines have induced mining men to go
deeper with a surer hope of success. We no
longer scratch over the surface, and consider
a mine worked out if it gives out at two hun-
dred feet. In Nevada the shafts are many of
them below two thousand feet, and most of the
machinery lately put up is calculated to work
the mines at a depth of four thousand feet.

It was supposed at one time that by the regular
increase of temperature with depth, mining
below two thousand feet would be almost im-
possible, and so expensive as to be impracticable.
Practice proves this idea to have been fal-
lacious, for by our shafts and various other
means, the heat in the lower levels is decreased,
and the miners made more comfortable. Another
fact indicating the faith of capitalists in mining
investments, and proving that as a business
mining is gaining strength among us, is that the
mills now made are larger and heavier than
ever, the hoisting and pumping gear heavier
and stronger, and the buildings and surface
works are put up in a manner indicating that
the owners intend to work properly. Deep
mining—deeper than the world ever saw before,
is now being done, and the miners look with
as much confidence on working a four thou-
sand foot shaft as they do in the two thousand
foot workings to-day.

Bullion Product.

Naturally, we look to the results of the year
as the measure of the success of any business.
In 1874 the product was \$74,401,055, and last
year it was \$80,889,037. In 1873 the yield was
\$72,258,693, and was referred to as the largest
in one year in the history of the coast. The
accuracy of this statement has been questioned,
and the yield of 1853 referred to as being
greater. Dr. Linderman, Director of the U. S.
Mint, whose information is probably as reli-
able as may be had, names \$65,000,000 as the
amount produced in 1853, and that amount
was not exceeded until 1873, which was ex-
ceeded by 1874, and now again by 1875.

The returns for the year 1875 are \$6,487,-
982 in excess of 1874, as will be seen from the
following report of John J. Valentine, super-
intendent of Wells, Fargo & Co.'s express.

EDITORS MINING AND SCIENTIFIC PRESS: We enclose
you herewith a copy of our Annual Statement of Precious

Statement of the amount of Precious Metals produced in the States and Territories west of the Mississippi river during 1875.		Total.	
States and Territories.	Amount.	1874.	1875.
California.....	\$1,847,010	\$1,847,010	\$2,300,231
Colorado.....	769,183	769,183	35,432,230
Idaho.....	74,517	74,517	1,155,635
Montana.....	1,168,698	1,168,698	1,830,000
Nevada.....	2,293,609	2,293,609	6,973,603
Utah.....	43,886	43,886	8,911,498
Arizona.....	22,000	22,000	6,299,817
British Columbia.....	2,027,412	2,027,412	2,408,671
Total.....	\$23,640,984	\$23,640,984	\$74,401,055

Metals produced in the States and Territories west of the Mississippi river, including British Columbia and the

West Coast of Mexico, during 1875, which shows an ag-
gregate yield of \$80,889,037, being an excess of \$6,487,982
over 1874, the greatest previous annual yield in the
history of the Coast. Nevada, Colorado, Mexico, Oregon,
British Columbia, Montana and Arizona increased,
while California, Idaho, Utah and Washington de-
creased. The increase is actual except for Mexico,
Oregon and Arizona, where it is apparent rather than
real, as compared with other years, a regular product
being accounted for and reported herein, hitherto
omitted. The decrease in California was in the main
accounted for by a stunted supply of water for placer and
hydraulic mining. The increase in Colorado and Nevada
is notable, also the fact that Nevada yields more
than half of the whole product of the country. Prof. R.
W. Raymond credits New Mexico (omitted in our state-
ment) and Arizona combined, with \$987,000 which is a
liberal allowance. We have been unable to obtain any
data that justifies a showing so favorable. The present
prospects indicate an aggregate yield of \$90,000,000 for
1876, of which Nevada will doubtless produce \$50,000,-
000. Respectfully yours,

J. J. VALENTINE, General Superintendent.

Nevada again heads the list and California
comes second. The increase in Nevada over
1874 is \$5,026,145. The decrease in California
has been \$2,547,380; Oregon has gained \$455,-
976; Washington has decreased \$73,603; Idaho
has fallen off \$325,102; Montana has gained
\$134,111; Utah has fallen off \$223,784; Arizona
has gained \$83,028, although we do not con-
sider the figures from that section as reliable
as others, as so much bullion goes through private
hands, of which Wells, Fargo & Co.
would have no account. Colorado has gained
\$2,108,412; Mexico has gained \$1,699,773.
The figures from Mexico cannot be considered
as full as they should be for the reasons given
concerning Arizona. British Columbia gave
\$140,396. The total increase of all over last
year amounts to \$6,487,982.

	1873.	1874.	1875.
California.....	\$18,062,923	\$20,300,231	\$17,763,151
Nevada.....	35,254,507	35,432,230	40,478,359
Oregon.....	1,376,339	609,070	1,165,046

Totals.....\$72,258,693 \$74,401,055 \$80,889,037

This makes a total bullion product for three
years, including the west coast of Mexico and
British Columbia (which do not properly be-
long in the table), of \$227,548,785, a very good
showing for a productive industry.

The receipts of treasure in this city for 1875
is given as follows by Wells, Fargo & Co.:

FROM THE NORTHERN AND SOUTHERN MINES.		Gold Bars.		Coin.		Totals.

Redington Quicksilver.....	30,000
Rye Patch.....	30,000
West Comstock.....	50,000
Totals.....	13,306,000	11,803,000	15,235,100

An increase is shown in the gross amount of dividends this year, although they have been paid by fewer mines. The magnificent dividends of the Consolidated Virginia mine, however, exceed any ever paid by any mining company in the United States, and probably in the world. In addition to the very heavy expenses of such a well equipped mine, and the serious drawback of the fire, the mine has paid \$12,960,000 in dividends, with the prospect of increasing the amount this year. More information concerning this mine is given further on in this article.

California.

This State shows a falling off in the bullion product for 1875, the deficiency being caused principally by the light rains of the winter and the consequent decreased water supply for hydraulic mining. The rainfall so far this winter has been good, and without doubt next year will again see an increase of bullion. Of quartz mines in this State but few have been productive. Those in Nevada county have probably done the best, but the results are not encouraging. The Idaho mine produced \$495,669 in 1875, and paid in dividends \$174,050, but the annual report (published in this journal recently), was not encouraging as to future prospects. The Empire, in the same locality, paid \$50,000 in dividends in 1875. The New York Hill mine is said to have plenty of rich ore, but as yet has not been put on a dividend paying basis. The Fryer process, of which so much is expected, will shortly be in active operation in Grass Valley, and many of the mines which are not profitably worked by present systems are expected to pay by the new process. If it succeeds there, many other districts in California will be revived which now labor under similar disadvantages.

Panamint district, from which so much was expected, did not come up to anticipations last year, although a large amount of money was invested there in building roads, putting up mills and other improvements. The deposits were not so large as at first supposed, and the ores of a lower grade. Many of the people have removed from there to Darwin, Inyo county, where considerable work is being done. The ores are of a smelting character, and if balt what is said is true, the district must be a rich one. Smelting furnaces have been erected and just now the camp is in a flourishing condition.

The mines of Amador county, especially her quartz mines, have been worked during the year with indifferent success, but the close sees improving tendencies in the Amador Co. and the Phoenix. The Oneida paid \$45,000 in dividends, but none since August last.

The Oroville Mercury says that within the past few years a number of quartz mills have been built in Butte county and quite a start made in this kind of mining. From the character of the quartz along the northeastern part of this county, there can be no doubt but what, in coming time, a large number of mills will be kept constantly running. The heavy rains which have fallen this winter will furnish an abundance of water to work the hydraulic claims.

In Tuolumne county, the Independent says, in speaking of its mines: The Confidence, after a suspension of over two years, has again started up with good paying ore. The Riverside, after paying all running expenses, erecting a good ten-stamp mill with other improvements, has come upon a streak of poor ore, and upon this basis the mine has shut down for the present. The Sonleby mine, under similar circumstances, closed down a number of years ago, started afresh and is now a good paying property. The Hunter mine, after paying handsomely and taking out big gold, suspended. A tunnel has recently been run, striking in under the old works at a depth of several hundred feet, and specimens we have seen are very rich in free gold. The Golden Gate company are erecting new machinery for saving sulphurets, which are found in great abundance in the mine, and will soon be in good working order and paying handsome dividends. The

Marks & Darrow, Lady Washington, Grizzly, Chapparral and many others we might name are undergoing the work of development with great encouragement for success. The Spring Gulch works quietly bring its amalgam to town without any fuss. The Nouparril, under the management of Superintendent Duprat, near Garrote, has just had a big clean-up, and other mines in that part of the country are looking well. Of other parts of the State the quartz mining interests present few new features worthy of note.

The gravel mining interests of the State are still as important as ever, and it is the opinion of many that we have only just commenced our hydraulic mining operations, so great is the extent of auriferous gravel in the State, water only being needed to develop the riches. Details of operations at the gravel mines are difficult of access, as the mines are generally owned by close corporations, which publish no statements, and only those interested in them are cognizant of the result of operations. This winter, with its abundant water supply, most of the mines are working profitably, and a long and prosperous season is expected.

Nevada.

The mining interests of the State of Nevada were never in a more flourishing condition than at present, with the noble Comstock porriagies accumulated wealth in the channels of trade. Of the district outside of the Comstock, however, little can be said in the way of improvement.

At White Pine, when the camp was just about abandoned, a strike was made in the Eberhardt and Aurora mines, belonging to an English company, which it is supposed will put the district on its feet again, as it gives assurance that the deposits in the hill are continuous, and will be found with depth. At Pioche, little encouragement has been met with, for although the Raymond & Ely has produced considerable ore, no new discoveries have been made. If they find it possible with present pumping appliances to prospect below the water belt, they may find something which will make a great difference in the future of the camp.

Eureka district, next to the Comstock, is the most productive in Nevada. It produced 11,212 tons of bullion, which may be rated at least at \$225 per ton, thus showing a yield of about \$2,524,700. This is exclusive of the refined bullion forwarded by the Richmond, an English corporation, and which aggregated a very considerable sum. The principal mines are the Eureka Consolidated, Richmond, K. K. Con., Atlas, Jackson and Adams' Hill. In the latter some very promising developments have been made on the 150 and 200-ft levels, which give every assurance of magnifying into a rich and extensive deposit. The Eureka is yielding a plentiful supply of ore, and producing bullion in large quantities.

The Gila district, which lies a short distance from Eureka, has two bullion producing mines within her boundaries—the Gila and Tybo Con. The former is giving a yield in five and a half months of \$284,292.41; the latter had only begun the crushing of its rock the last part of the year.

One of the most promising new mining districts is located at Belleville, Esmeralda county, embracing several mines, the most productive of which is the Northern Belle, that yielded \$851,000 in eleven months of the year, and disbursed \$350,000 in dividends.

The Bonanza.

The most important matter to the mining interest of the country which has occurred of late years has been the development of the immensely productive bonanza on the Comstock. The results of the work done there have been such as to astonish the world and turn the attention of thousands to mining matters who never before gave them a thought. The great disaster of the fire at Virginia was a terrible setback, but energy, perseverance and plenty of money soon repaired the damages. The fire that swept a road half a mile in width through the heart of the city, and laid in ruins the complete and costly mills and hoisting works of the Consolidated Virginia, California and Ophir mining companies, rendered it next to impossible to reach the underground regions of those mines for some weeks.

Everything is now in working order again, and the Consolidated Virginia did not even stop paying its regular dividends. The prospects at the present time are decidedly flattering. The California mill just completed and started into operation, gives at once a monthly addition of \$800,000 or more to the bullion product of the country. The ore yield of the Ophir will be resumed in a day or two under the most flattering auspices. The Consolidated Virginia is constantly increasing its immense yield, and the great C. & C. shaft is being hastened as fast as unlimited means will allow, to the point where it will form a most important outlet to the wilderness of rich ore now waiting in the depths of the great bonanza. The Imperial is showing well, and important developments are eagerly looked for in the cross-cutting just commenced at the lower level of the Yellow Jacket. The consolidation already agreed upon of all the small mines of Gold Hill, into three or four large and effective ones, is an important and influential move. Belcher is yielding well, and improving. Overman, Silver Hill, Globe Consolidated, and other mines are showing good and improved ore developments, and all along the line the outlook is highly encouraging and propitious.

Many mines are now beginning to yield ore that have never been productive, and companies that for a time have been delving in

barren rock are again finding ore. The Belcher company has been able to resume the payment of dividends; at no distant day the Ophir will pay dividends—indeed, but for the fire, would have already paid one or two dividends—and dividends may be expected from several other mines. In April the drift from the O. & C. shaft will tap the 1500-ft level of the bonanza mines. When this shall have been done the whole of the compartments of the Consolidated shaft and the whole power of the works can be devoted to the hoisting of ore from the two mines—Consolidated and California. The huge mill of the former company will be rebuilt, and a second large mill will be put up by the latter at the O. & C. shaft. Then indeed will the bonanza begin to bleed.

We are unable to give space to any detailed description of the bonanza mines, and content ourselves in giving a table published in the *Alta*, showing the production of some of the noted mines in the past year.

												\$20,000,653.

The Consolidated Virginia.

The richest mine in the world, made a most magnificent showing last year. Throughout the year there has been no cessation in the payment of the regular monthly dividends, which for the last ten months have been at the rate of \$10 per share. In October last the very disastrous fire which destroyed so great a part of Virginia City, swept away fine and extensive hoisting works and buildings, together with a vast amount of supplies of various kinds, and the splendid 60-stamp Consolidated and California mills (the latter of which was about starting up) materially affecting the crushing facilities. The misfortune compelled the stoppage of nearly all underground work, and necessitated the cessation of bullion shipments until the hoisting works and other necessary buildings could be replaced. This has been done, and new works and buildings superior to those destroyed were erected in the short space of two months.

During the past year 169,307 tons of ore have been extracted from all the levels of the Consolidated Virginia mine, and 169,094 tons have been reduced, which yielded \$18,731,653 in bullion. There are now in the ore house and at the mills 2,988 tons, valued by assay at \$478,080. This ore has been taken from the 1200, 1300, 1400 and 1500-ft levels, including a small quantity which has been gathered in the explorations which had been made on the 1550-ft level.

The cost of the joint shaft has been so far \$436,183.13. After the connection with the C. & C. shaft has been made, the superintendent thinks the hoisting capacity will be 2,000 tons per day. The total receipts at the mine for the year were \$17,060,855.88, of which \$16,953,771.39 was from bullion. The dividends amounted to \$12,204,000 for the year.

A two story building, 100 by 50 feet, is in the process of erection, to be used for the assay and bullion department, and it is now about one-half completed. When finished there will be room and facilities for melting and assay-

ing \$5,000,000 of bullion per month. The present estimates of ore in sight give a value of \$300,000,000. The new mill, with a crushing capacity of 300 tons per day, will increase the amount of ore extracted and reduced nearly one-half, and will add over \$800,000 per month to the yield of the mine. This will give a total yield for each month of \$2,500,000, and will almost, if not quite, permit of doubling the usual dividends of \$10 per share.

Other States and Territories.

Arizona in its bullion yield does not make that exhibit which should really be expected from that Territory. Within her borders are some very rich mines, which will, as soon as the machinery can be obtained requisite for working them, produce bullion in such large quantities as will attract more than common attention.

In Idaho there was not much of encouragement last year. Some of the mines are rich, but mismanagement and consequent assessments have brought the properties there into bad odor.

The Colorado production has increased, and the reports from there continue as glowing as ever. The great want of the Territory is capital, of which it has as yet but little.

Utah, although it produced \$6,145,211, is not in a prosperous condition as to mining interests. The Emma mining accident did much to hinder capital coming to Utah, and it is just now in rather bad odor. The Utah *Mine* gives the mineral products for 1875 as follows: Base bullion, \$4,086,900; silver lead, \$532,000; copper, \$87,948; copper ore, \$14,200; silver bars, \$637,763; gold dust, \$35,800; ore on dumps, \$750,000; total, \$6,145,211.

Oregon is not considered much of a mining State, although there are several good paying claims there, but agriculture is ahead in that section.

Quicksilver and Coal.

The production of Pacific coast coals has been as follows: Bellingham bay, 10,440 tons; Coos bay, 29,078 tons; Seattle, 59,327 tons; Port Townsend, 37 tons; Mount Diablo, 142,808 tons; Rocky mountain, 53 tons; total, 538,785 tons.

Of quicksilver, the feature of the year has been the great production, double that of any year for the past few years, and the rapid decline in price, which has accompanied this production—opening at \$1.55, the first decline was to \$1.30, then to \$1, then to 90c, subsequently to 75c, 70c and 65c by the first of July. The market then took an upward turn, reaching 70c in July, declining to 62½¢@65c in August. It then took another upward turn, reaching 80c@85c by the close of September. In October it declined to 67½¢@70c; in November to 65c, and in December to 60c@62½¢. The increase of production this year has been great. The *Bulletin* gives the following as the production:

Products		
New Almaden, flasks	13,648	Brought forward..... 46,842
New Idria.....	8,500	Sunderland..... 1,500
Redington.....	5,080	Cleveland..... 714
Sulphur Bank.....	5,213	Buckeye..... 700
Guadalupe.....	3,415	Manhattan..... 437
Great Western.....	3,384	Great Eastern..... 413
St. John.....	2,100	Phoenix..... 300
Oceanic.....	2,000	Various..... 3,000
Carried over.....	46,842	Total..... 63,708

The New Almaden mine continues to be the chief source of supply, its product having been increased fifty per cent. during the past year.

Conclusion.

In conclusion we append a few remarks on mining stocks, which, whatever may be said to the contrary, exercise a very important influence on the mining interests. According to a compilation of the transactions at the San Francisco Stock Board, the business for the past year has been fully up to the average of the previous year, if we allow for the absence of sales in September, during which Board sales were suspended on account of the financial panic. The sales of the Board for the past four years compare as follows:

1872.....	\$189,900,000	1874.....	\$260,500,000
1873.....	146,400,000	1875.....	320,200,000

There were 180 stocks dealt in at the San Francisco Board last year, and the total sales foot up 8,287,000 shares.

We give on another page a table compiled by the *Stock Report*, showing the highest and lowest prices of mining stocks during the past twelve months, giving place only to those stocks which are in the list of the San Francisco stock and exchange board. The prices of mining stocks have now such an influence on the mining interests of the coast, that most people look to the lists as an indication of the state of mining affairs. Although this is by no means a just view to take of the matter, many suppose that the fluctuations of stocks indicate to some extent the varying bullion product of the mines. The fact is that a very large proportion of the mines called at the boards are those on the Comstock lode. About half a dozen California mines are called, but they have no prominence. The Idaho mines, what few there are, are under disgrace from repeated assessments, and transactions on them are comparatively small. The great bulk of business is in Comstock shares, which, however, by no means vary according to the merits of the mines.

As will be seen by even a casual glance at the tables, the transactions this year have been subject to violent fluctuations. By following the lines along from left to right, it will be noticed that a gradual decline has taken place from month to month, until the sudden break when the Bank of California failed and the panic came. Since then there has been no very great advance to speak of, and few of the stocks have regained their places as yet.

MINING COMPANIES.A Mining and Civil Engineer, of long experience,
selected in Europe and America, well acquainted with
correct management of mines and mills, practised in
projecting and constructing mining and milling ma
chinery, and especially machinery for mechanical ore
concentration, is open for re-engagement, and would
prefer the task of constructing works for mechanical
concentration of low grade ores on a well developed
mine, or of remodeling ineffective works in the ore
milling line for successful operation. Apply to

SEND FOR CIRCULAR

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you
sent to Baldwin & Tabor, Manchester, N. H. We ran it most
all day, and ground 60 bushels corn per hour. The mill you
sent us at Haverhill, Mass., for A. S. Hook, is doing wonder
fully. It is grinding on an average 2,500 lbs. good meal per
hour, and has ground 2,800 lbs. in an hour. It is driven by an
engine with a 9-in. cylinder, and takes the place of a 30-in.
mill of another kind that, when doing its best and loading
the engine with all it could carry, only ground 1,500 lbs. per
hour. If there is a mill built that can beat that we would be
pleased to see it brought out."

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently
introduced for general family use in San Francisco and
neighborhood, is already in great demand. It is now the
intention of the manufacturers to introduce it all over the
Pacific Coast, at prices which will bring it within the reach
of every household.
It is unequalled for cleansing Woolen Fabrics, Outtery,
Carpeting, Crockery, for Scrubbing Floors, Washing Paint,
Removing Grease Spots, Shampooing or Bathing.
It renders water soft, and imparts a delightful sense of
coolness after washing.
DIRECTIONS.—For Laundry, use two to four table
spoonfuls to a washful of water. For bathing, use one
tablespoonful in the bath tub. For removing grease spots,
apply with a brush, undiluted, and wash with water after
wards. For stimulating the growth of plants, use a few
drops in every pint of water used in watering.
PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bot
tle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical pur
pose, fertilizing, and the preparation of artificial manures.
AMMONIACAL PREPARATION for the prevention and
removal of boiler scale. CRUDE AMMONIA, for general
manufacturing, and PURE LIQUOR and AQUA AMO
NIA for chemical and pharmaceutical purposes.
Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.
5vwhpSan Francisco Cordage Company.
Established 1856.We have just added a large amount of new machinery of
the latest and most improved kind, and are again prepared
to fill orders for Rope of any special lengths and sizes. Con
stantly on hand a large stock of Manila Rope, all sizes;
Tarred Manila Rope; Hay Rope; White Line, etc., etc.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR
APPLICATION—requiring no thinner or dryer, and will
not spoil by standing any length of time.It is Cheaper, more durable, more Elastic, and pro
duces a more Beautiful Finish than the best of any
other Paint.It will not Fade, Chalk, Crack, or Peel off, and will
last twice as long as any other Paint.In ordering White, state whether for Outside or In
side use, as we manufacture an Inside White (Flat) for
inside use, which will not turn yellow, and produces
a finish superior to any other White known.Put up in 1/4, 1/2, 1, 2 and 5 gallon packages, and in
Barrels. Sold by the Gallon.For further information send for Sample Card and
Price List, or apply to the office.OFFICE and DEPOT: FACTORY:

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes gray steam, passes to all the valves and cylinder at every stroke of the engine; glue tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

The Ingersoll Rock-Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS. Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and HAS AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

Gold, Legal Tenders, Exchange, Etc.

[Corrected Weekly by CHARLES SUTTO & Co.]

SAN FRANCISCO, January 19, 3 P. M.

LEGAL TENDERS to S. F., 11 A. M., 85% to 93%.	
Gold in N. Y. 112 1/2.	
Gold Bars, 850 to 900. SILVER Bars, 7 1/2 and 8 per cent discount.	
EXCHANGE on N. Y., 60-100 per cent premium for gold; on London bankers, 4 1/2; Continental, 4 1/4; Paris, 4 1/2; France, 4 1/2; Mexico, 4 1/2; Mexican dollars, three to five per cent discount.	
LONDON - Consols, 93 to 93 1/2; Bonds, 102 1/2.	
Gold and Silver in S. F., by the bank, per lb, 72 1/2 to 75.	

A WORKMEN in one of the Eureka furnaces dumped a slag-pot filled with liquid fire into a bank of snow the other day, causing an explosion which was distinctly heard all over town, and totally demolishing the slag-pot, though fortunately not injuring the workman, except by a big scare.

It is reported that the bluffs at the Klamath Bluff mines caved in recently, killing three white men and two Chinamen.

Silence that terrible enemy of life, a had cough, with HALE'S HONEY OF HOREHOUND AND TAR, otherwise the cough may soon silence you.

Pike's Toothache Drops cure in one minute.

WOODWARD'S ORCHIDS enhances an Aquarium, Museum, Art Gallery, Conservatory, Tropical House, Menagerie, Seal Ponds and Skating Rink.

1876. Scribner's Monthly. 1876.

We invite the attention of the public to SCRIBNER'S MONTHLY, which now deservedly ranks among the BEST ILLUSTRATED MONTHLIES OF THE WORLD.

The papers illustrative of American scenery, which have appeared in its pages, among which were included "The Wonders of the Yellowstone" and the "Grand Canon of the Colorado," have won widespread admiration on both sides of the Atlantic; and "The Great South" articles, with their beautiful engravings, have been re-issued in book form in both Great Britain and America. For the coming year we have broader plans than ever before. The magazine will be enlarged, and there will be THREE REMARKABLE SERIAL STORIES BY AMERICAN WRITERS.

"Gabriel Onroy," by Bret Harte.

Of which the Boston Post says: "It is a serial that will make every new number of SCRIBNER'S eagerly sought for, if it had nothing else to recommend it."

The Canadian Illustrated News predicts that "we have found at last the American novel."

The Louisville Courier-Journal says: The second installment is even stronger than the first, justifying all that was looked for.

We begin in January.

"Philip Nolan's Friends,"

By EDWARD EVERETT HALE.

This is a historical romance. The scene is laid in the South-west, at a time when that territory was first Spanish, then French, and then American, and when war was imminent, to obtain control of the mouth of the Mississippi. It is likely to be the great romance of the Mississippi valley, as "Gabriel Onroy" will be of the Pacific slope.

"That Laes n' Lawrie's,"

By FANNY HODGSON BURNETT.

The friends of "SCRIBNER" who have read "Sully Tim's Trouble," "One Day at Arlo," "The Fire at Orantley Mills," and others of Mrs. Burnett's short stories, will not need to be assured that they have a rare treat before them. The scene of the new novel is laid in an English mining town, and from the first page to the last the interest is unflagging.

Among other notable papers we mention the following: A second "FARMER'S VACATION," by Col. GEORGE E. WARREN, descriptive of a row-boat ride of two hundred and fifty miles in one of the most fertile and interesting of the vine-growing valleys of Europe—a region never seen by the ordinary traveler, but full of interest, in its social and industrial aspects. A rare collection of REVOLUTIONARY LETTERS. A SERIES OF ILLUSTRATED ARTICLES ON AMERICAN COLLEGE. The series includes William and Mary, Harvard, Yale, Michigan State University, Wesleyan University, Amherst Agricultural College, Princeton, Union, Bowdoin, Trinity, and other typical institutions of the country. Elegantly illustrated articles on OLD NEW YORK, illustrated papers on AMERICAN CITIES, etc.

The editorial control and direction of the Magazine will remain in the hands of Dr. HOLLAND, who will contribute each month editorials upon current political and social topics. Our readers may look to "TOPICS OF THE TIME" for healthy opinion; "THE OLD CABINET" for pure sentiment; "HOME AND SOCIETY" for graceful economy; "CULTURE AND PROGRESS" for criticism; "THE WORLD'S WORK" for industrial intelligence; "BRIC-A-BRAC" for wit and innocent pleasantry.

SCRIBNER'S MONTHLY is now recognized, both in this country and in England, as the great representative American Magazine.

Encouraged by the favor accorded to it by a generous public, we shall aim, during the Centennial year, to eclipse its former achievements in both its literary and Art departments.

SCRIBNER is sold by all First-Class Booksellers and News-Dealers.

Price \$4.00 a Year; 35 cents a Number.

The 10 vols. complete, Nov. 1870, to Oct. 1875, bound in maroon cloth, \$30.00. Same bound in half morocco, 30.00. Vols. given in November and May. Any of the earlier volumes (I to VIII) will be supplied separately to parties who wish them to complete sets at this rate, i. e., cloth, \$2.00; half morocco, \$3.00.

Booksellers and Postmasters will be supplied at rates that will enable them to fill any of the above offers. Subscribers will please remit in P. O. money orders, or in bank checks or drafts, or by registered letters. Money in letters not registered at sender's risk.

November and December numbers FREE TO ALL NEW SUBSCRIBERS for 1876.

SCRIBNER & CO., 743 Broadway, N. Y.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company—

Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte County, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-eighth day of December, 1875, an assessment, No. 35, of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, room 13, Safe Deposit Building, No. 328 Montgomery street, San Francisco, Cal. Any stock upon which said assessment shall remain unpaid on the twenty-ninth day of January, 1876, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Saturday, the nineteenth day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

C. H. BOGART, Secretary. Office, room 13, No. 328 Montgomery street, San Francisco, Cal.

Mariposa Land and Mining Company of California.

Location of works, Mariposa county, California. Notice.—There is delinquent upon the following described stock, on account of assessment (No. 3), levied on the 30th day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

COMMON STOCK.

At a Stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREES.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed)

LORENZO SAWYER,

Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just as fast as the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringing lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, [durability] and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim.

Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

Over 8,500 in Successful Use in the United States.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

1729-3m

CAST STEEL SHOE & DIE CO., Room 14, Academy Building, S. F.

SAVE \$50! WHY PAY \$85?

SEWING MACHINES.

REDUCED PRICE, \$35.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines.

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No tacking required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc. Send for Circulars.

HALL TREADLE MANUFACT'G CO., 17 New Montgomery St., S. F.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

WITH
LATE
IMPORTANT
IMPROVEMENTS.

Mortiser.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. *Best Prices reduced to 15 per cent. less than Eastern list.* We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. Mutual Benefit Life Insurance Company

NEWARK, N. J.

Assets, January 1st, 1875, - - - \$30,533,429 94

LEWIS C. GROVER, Pres't. L. SPENCER GOBLE, Vice Pres't.
Edward A. Strong, Sec'y. Bsnj. C. Miller, Treas. B. J. Miller, Actuary.

The following is a summary of the business of this Company from May 1, 1845:

Total Receipts,	\$74,397,520 70
Paid Losses and Endowments,	17,187,583 28
" Dividends or Return Premiums,	16,362,010 85
" Surrendered Policies,	3,714,825 68
" Expense—Management, Commissions, Taxes, etc.,	7,471,171 52
The Ratios are:—	
Retained for Insurance Fund and Surplus	\$39.07
Returned Members and Families	50.09
Expenses,	10.04

These results are more favorable to the Insured than those presented by any Company in the World.

ALL KINDS OF APPROVED POLICIES ISSUED.

Dividends paid annually, or they can be applied on the Accelerative Endowment Plan, as ORIGINATED BY THIS COMPANY, to which particular attention is called.

ACCELERATIVE ENDOWMENT PLAN.

The plan is intended to meet the wants of those who wish protection for their dependents in case of premature death, and at the same time to make a wise provision for themselves in the event of surviving the productive period of life.

The plan proposes that instead of using dividends in reduction of the annual premium, the insured may at his discretion, pay his premiums in full in cash, and surrender his dividends to the company. In consideration of this surrender, the company will agree to pay the sum assured when the policy holder shall have attained a certain age, or at his previous death, instead of at death only thus enabling him to procure an Endowment Policy at the usual rates charged for policies payable at death only.

If the policy is already an endowment, payable at a given age or previous death, the surrender of the dividend will enable the company to agree to pay the policy at a still younger age.

Advantages of the Accelerative Endowment Plan

Over any other yet offered to the public, will be apparent when the following features are considered:

It can be applied to any policy, whether "Life" or "Endowment," to old business as well as new, where there is no premium loan, or where the existing premium loan shall be paid off.

It enables one to obtain an "Endowment" policy at the usual "Life" rates.

The expenses incident to this form of "Endowment" insurance, being no greater than in case of "Life" policies, its superiority to the old style endowment will be readily perceived.

It not only has the effect of constantly reducing the age at which the company will agree to pay the policy, but also, every dividend so applied becomes itself the source of future surplus, thus causing the dividends to increase much more rapidly from year to year than would be the case if they were used in payment of the annual premiums.

The assured can, in any year, apply his dividend in payment of premium, and allow the time at which the policy matures to remain as at the previous year's settlement.

As each dividend is surrendered, the company will make a positive agreement as to the time at which the policy will be paid, and the amount payable at such time.

If at any time the assured becomes disappointed or dissatisfied with the plan, he is at liberty to use his future dividends in payment of premium, and to retain all the advantages accruing from the surrender of past dividends.

If at any time the party should be unable or unwilling to continue payment of premiums, the company will, within three months from the date of lapse, allow the equitable value of the policy in paid-up insurance.

The Mutual Benefit Life Insurance Company issues Policies insuring the lives of healthy persons residing in any part of the United States.

JAMES MUNSELL, Jr., Agent of Insured.

And Acting Agent for persons desiring Life Insurance.

224 Sansome Street, San Francisco.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of a new chimney and furnaces for the treatment of rebellious ores.

Office—439 Bush street, S. F.

VOLUME XXIII
Number 5.

The Fryer Process.

So much interest has been manifested in the Fryer process of working ores, and so much anxiety to learn the details, that we take pleasure in presenting to our readers this week a detailed description and engraving of the furnace used in the preliminary stages of the process. This will be followed in due time by a full description of the whole method, with illustrations showing the details of the other machinery, all of which is novel and different from what has heretofore been in use. The publication of this description, with the drawing of the furnace, is advisable in consequence of the false impression conveyed by the publication of what purports to be an abstract of Fryer's first patent. We corrected this erroneous impression in our last issue, and those interested can be convinced by examining the boxes of ore in the different stages of the process now at our editorial rooms.

In order that our readers may learn what Mr. Fryer claims, we give in full the following description, precisely as prepared for the specification for foreign patents, being a little different from the American patent in detail.

The object of this invention is more especially to facilitate and reduce the cost of the extraction of the gold and silver which is contained in quartz, but it may also be applied to the separation of the noble metals from other ores in which they may be contained with the base metals.

The invention consists in a furnace of upright cylindrical form, which has a double wall or shell of boiler plate or other iron for containing water and steam, and a suspended invertible or removable bottom, and has in its upper part a cone, around which the gaseous products of combustion in the furnace may escape to a stack above, and upon the exterior of which is delivered water, which falls over its edges and meets the gaseous and volatile products escaping from the furnace, and condenses certain metallic and other portions of said products, which fall with the said water and are collected therewith in a suitable receptacle, while the ore is being roasted in the furnace by the combustion of wood, upon which the said ore is deposited therein. Air is freely supplied to the said furnace through an annular opening provided around its removable or invertible bottom, for the combustion of the fuel and the oxidation of the oxidizable portions of the ore; and this supply of air is or may be increased by the steam which is generated by the heat of the interior of the furnace from the water in its double shell, and introduced in jets to the stack to act as a blower, the water also serving to prevent the rapid burning or oxidation of the inner shell or wall of the furnace. The suspended removable or invertible bottom serves to permit the rapid discharge of the contents of this furnace after the roasting has been completed. By the roasting process in this furnace the noble metals are to such an extent separated from the mineral matters and the base metals which are oxidized by the roasting process, that their complete separation may be easily effected by pulverization and subsequent amalgamation, the ore having been brought to such condition by the roasting process that its complete reduction to an exceedingly fine powder is very greatly facilitated.

The invention is illustrated in the accompanying drawing, which represents a central vertical section of the furnace.

FURNACE USED IN PRELIMINARY STAGES OF THE FRYER PROCESS.

The body, A, of the furnace, constituting the furnace proper, is of upright cylindrical form, open at the top and bottom, and suspended on or in a frame work, B, by legs, C. This furnace is constructed of boiler plate or other iron, with a double shell, D E. Between the shell, D E, a water and steam space is provided, the object of which is, in the first place, to pre-

vent the inner shell, E, from rapidly burning out; and in the second place, to provide steam with which to supply a steam jet blower, F, located in the stack S, above the furnace.

H is the bottom of the furnace, made in the form of an open vessel of an internal diameter larger than the external diameter of the body of the furnace, and constructed with a double

shell, having a water space to prevent rapid oxidation of the interior. The said bottom is suspended from the frame, B, by rods, I, connecting therewith by trunnions, J, and with apparatus overhead, by means of which the said bottom may be raised, and lowered at pleasure. K is a double-shell chamber situated at the top of the body of the furnace, and through the inner shell of which the gaseous products of combustion and volatile matters from the furnace pass to the stack, S, which is erected above said chamber. The space between the two shells of this chamber, K, contains water, which prevents the burning out of the inner shell.

L is a cone, which is located as shown, over the upper portion of the inner shell of the chamber, K, and upon which is delivered a stream of water through a pipe, M, which water comes in contact with said products as they pass in the direction indicated by the arrows, and afterwards falls into the space between the inner and outer shells of the chamber, K. N is an overflow pipe for conducting off the water from the space between the shells of the chamber, K, after it has performed the operation of condensing the volatile metalloids and some other products of combustion which have been evolved from the furnace and which are collected in the said space. O is a pipe for conducting steam from the space surrounding the body of the furnace to the blower, F. P is a pipe for feeding water to the above mentioned space.

The operation of the furnace is as follows: Wood is delivered to the furnace through the door, Q, until the same is filled to about the height shown, when the quartz or ore to be treated is delivered in the same manner, in lumps of any size that will enter the furnace, on to the top of the wood, which is then ignited at the bottom. The result is that the principal portion of the wood is converted into charcoal before a great amount of the same is consumed; after which the whole charge is gradually raised to a very high temperature in the presence of a large flow of air entering the furnace between the body, A, and the bottom, H, as indicated by arrows—the influx of said air being urged by the action of the blower as soon as sufficient steam is generated. The effect is that the sulphur and other volatile matters are mostly expelled, while the base metals are converted into oxides in the furnace, leaving the noble metals in comparatively a free state for amalgamation.

The relative quantities of ore and fuel supplied to the furnace may be about one and a quarter cords of wood to four tons of ore, or in like proportion according to the capacity of the furnace; but these proportions may be varied according to the nature of the ore under treatment.

After the charge of fuel has completely burned out, the bottom, H, is lowered and turned upon its trunnions sufficiently to precipitate the contents of the furnace into a pit, R, below, or into or on any other suitable place or receptacle, from whence it may be gathered for further treatment. The bottom is then replaced in the position shown in the drawing, when it is ready to receive another charge for a repetition of the operation.

SLEIGHING is again good at Virginia City, and considerable ore is being hauled on sleds. Icicles from five to ten feet long are also a prominent feature of the place at present, hanging from the roofs of every house.

THE smelters and silver mills of Utah propose giving the product of one day's run to swell the exhibit at the Centennial.

Working Quicksilver Ores.

We give herewith an article from the *Berg und Huettenwesenmaennischen Zeitung*, the translation of which has been kindly furnished us by Mr. J. B. Randol, manager of the New Almaden mine. It describes a new process of working quicksilver ores, proposed by Emil Pellet.

In the *Revista Minera*, Vol. XXII, as also in this journal, Vol. XXXI, 1872, on the 410th and following pages is mentioned a new process for the reduction of cinnabar ores, by Emil Pellet, and on the 309th and following pages of the first mentioned publication, is a review by Ygnacio Gomez Salazar, of the results of the trials of said process, made in the year 1869, at the works of Almaden, in Spain, under the direction of the mining inspector, Don Jose Monasterio y Correa, and which appears in his official report, the statements of which may prove of interest, as no further details about this process have been published since. In Vol. XXIX, 1871, of the *Revue Universelle des Mines*, etc., by de Cuyper, is on the first and following pages a communication about the quicksilver mines of Almaden, by Jose Monasterio y Correa, and at the end of it is promised, also, a description of the process employed in Almaden for the reduction of ores, but as this has not appeared as yet, the following remarks of Salazar on the results which were produced by the experimental tests of Pellet's process may find a place here.

According to the statements of Salazar, Pellet asserted that he had discovered a process for which he claimed the following advantages:

1. No loss of quicksilver contained in the ore.
2. Curtailing of the expenses of working the ore and of fuel.
3. No losses of quicksilver by vaporization, explosion, or imperfection of apparatus.
4. Reduction of the ore in the state in which it is mined, wet or dry, in large or small pieces.
5. Uninterrupted working throughout the year, regardless of the state of the atmosphere.
6. Low cost of the apparatus and inconsiderable repairs.
7. Safety of the health of workmen.

These great advantages of the new process were considered for the works of Almaden of the greatest importance, and each one of the advantages claimed was regarded as meriting a reward; hence, the government of Spain willingly offered opportunities and means to test the new process at the reduction works of Almaden, under the management of Monasterio and Arceaga, who were directed to report upon the results in detail. Monasterio asserts in his report that all conjectures of the inventor of the tested process had proved themselves to be incorrect. The loss of quicksilver, which Pellet had promised to avoid entirely, had been found to be doubled. The cost of reduction had been four and a half times greater than the expenses of the old process, which had been used in Almaden over seventy years, and the escape of quicksilver (volatilization,) through cracks, and in every conceivable manner, had caused great losses. Neither in the dry nor in the wet state, neither in small nor in large pieces had they been able to reduce the ore as it had been mined; and after breaking with the hammer the ore had suffered losses in every state of the atmosphere in summer and winter; and also the health of the workmen who were employed for the Pellet process had suffered considerable injury.

According to the process, by Pellet, the distillation of the volatile parts of the ore is effected by means of a continuous roasting in place of the intermittent roasting and the condensation in the atmosphere is replaced by a condensation under water. Salazar further asserts that the process of Pellet respecting the two above mentioned deviations from the usual process of Almaden had been previously tried in Spain and other countries with unfavorable results. The use of water for the condensation of mercurial vapors could not properly be regarded as the invention of Pellet, for the use of rain had been proposed, but rejected, for the attainment of the same object; and the proposed condensation of these vapors through a mass of water of five millimeters did not promise favorable results. The application of a current of air, created by a ventilator, placed at the base of the furnace was neither new nor proper, and in the case under consideration did not serve its purpose, and the arrangement of the contrivance was like many others, whose main part consisted in a system of chambers. Based upon these facts, Salazar believes to be justified in regarding the process of Pellet as one which, although based upon good principles, through their misapplication formed an aggregation totally unfit for the accomplishment of the desired object.

In accordance with Salazar's assertion the unfavorable result obtained of the competitive trial at Almaden cannot be ascribed to the retention of means and resources, as an unlimited supply of them with most favorable opportunities for their application had been accorded to Pellet. He was permitted to make a preliminary trial, and to introduce for the decisive trial several important modifications, suggested by the results of the prior trial. Pellet's process of reduction was placed in comparison

with the results of a furnace in Idria, which produced less than the older furnace of Bustamante, and the competitive trial took place in the hot season, which is the most unfavorable season of the year for the Idria furnace. Balls of coal dust, which are always used in charging the Idria furnace, were omitted in the trial charge, for Pellet did not use them. This was a disadvantage for the Idria furnace.

Notwithstanding the equality of the charges placed in both furnaces, Pellet protested against the coat of cement with which the interior of the Idria furnace was lined. But to bring about in this instance also an equality, Pellet's furnace was also lined with a coat of cement. Pellet asserted that the above mentioned coat of cement belonged to his invention, and drew from this the inference that the unfavorable difference of the obtained results at the trial was owing to this trifling.

Salazar says he would not have mentioned this assertion of Pellet's if Monasterio in his report had not spoken in favor of it. But he would remark to both, that neither the cement nor its application belonged to the invention of Mr. Pellet, and that the cement coating of the furnaces of Almaden had been proposed many years previously by a mining engineer of Spain.

Omitting the other critical comments of the report of Monasterio, we shall make the following extracts from the communication of Salazar, page 392, etc., and 494 of the *Revista Minera*. The mind of Pellet was not set at rest by the failure of the trial of his process at Almaden, but he gave it another test at Albulon, to which Salazar had been previously invited, but the invitation was declined for the following reasons: Pellet had offered his process to the Spanish government in 1867, claiming for it the above mentioned advantages; he had requested the government to compare the results obtained by his process with those of the process then in use at Almaden; he had further requested the appointment of a committee of experts, and in case the committee should report in favor of his process to grant him a reward, which, according to the estimation of Pellet, would have amounted to 15,000,000 reales.

Regarding the improvements in the process of reduction and the preservation of the health of the workmen, the government had referred the petition to the highest mining authority, which had agreed with Pellet to test his process under the following conditions: The reduction of the quicksilver ore, taken from the same pile, should take place simultaneously in two furnaces, one to be constructed according to the direction of Pellet, and the others to be modeled after the furnaces then used in Almaden, and the obtained results to be placed side by side for comparison. Pellet had received, with the greatest readiness, during his presence of two years at Almaden, and even before the beginning of his principal trial, all the required means and assistance, and furthermore in a preliminary trial for the discovery of some possible defects, he had been materially aided. Workmen for the training in the work of the new process had been placed under his charge, and in every respect the greatest possible latitude in his actions had been granted to him. But notwithstanding these opportunities favorable to success, a large number of laborers had got sick and a smaller yield of quicksilver had been obtained, and without counting the costs of erection, the expenses had been greater than usual at the works of Almaden. Pellet had acknowledged the trial and the obtained results, but after an expiration of two years he had rejected the trial and had insinuated that Monasterio was responsible for the failure, and therefore he, Salazar, could not accept the invitation to Albulon. Salazar asserts further that the failures of both trials in Almaden and Albulon had not been sufficient to refrain Pellet from making a third trial. Pellet had transferred his invention to a company to which the Spanish government had granted a repetition of another trial. Salazar does not doubt that this would be another competitive trial, that one furnace would be constructed according to Pellet's direction, and the other after the Almaden old style, that in both the same quality of ore would be used, and that all necessary caution would be taken at the trial. He also thinks it indispensable not to lose sight of the experience already gained at the former trials, and to guard against any error which might give a right to the inventor to claim the premium of \$15,000,000 reales. He (Salazar) thinks the decision of the new trials of Pellet's process under all circumstances, as determined for the following reasons:

1. The appointed commissioners possess the most extensive knowledge of mining and reducing quicksilver ore.
2. In case this trial should result in favor of Pellet's process, it would be imperative that another trial should be ordered, to decide the contradictory results of the trials so far made.

In the following Vol. XXIII of the *Revista Minera* no mention is made of Pellet's process, with the exception of a single allusion to the first unsuccessful trial, and as Salazar (page 389, etc., of this Vol.), when speaking of some objections which had been made against the furnace of Bustamante, commends the said furnace, it would appear that the trial had not then taken place. Salazar will doubtless publish in the *Revista Minera* the results of the new trial as soon as it shall have ended, and will at the same time make publicly known the peculiarities of Pellet's process and the application of the contrivance employed.

Rich gold mines have been discovered on Upper Four Mile river, Colorado.

The Snake River Mines.

A correspondent of the *Idaho Statesman* writes of these mines as follows:

Work is being prosecuted vigorously on the various ledges; there are four companies "hard at it." Ruth & Heath have struck richer ore than even the best they ever had before; the fissure is true and well defined. The ore they now get will assay well up in the thousands. Some of the rock is literally held together by horn silver, and rich chlorides are as abundant as ever.

In the Picayune ledge, which is copper ore, and assaying up to \$150 in gold, Dave Bridgeman & Charley Sampson are preparing to run a tunnel to tap the ledge about forty feet from the surface. This ledge is about ten feet wide, and can be traced for over half a mile. There are three locations of fifteen hundred feet each taken upon it. First, on the discovery, by Hoover & Parker; second, Bridgeman & Co.; and the last, by Hon. Mose Biddy & W. Angle, of Horseshoe Bend.

On the Alpha ledge F. J. Parker is at present going it alone. The indications are more favorable than ever. The ledge is so wide that it has taken "beaps" of work to discover the best place to sink a shaft. The company having found it, they will shortly double the working power and work the best part of the winter.

William West will shortly go in on the Katie Halley ledge. At present Billy is trying to bring order out of chaos at the mouth of Brownlee creek, making a good wagon road, which, with the road the Union county (Ogn.) powers that be are making for Pine valley, will place us in direct communication with the Columbia river. There yet remains about ten miles of road to place us in communication with Boise City.

In this camp the bosom of mother earth is bare. Grass was never in better condition for stock. The weather is mild and we have good reasons for expecting a very open winter; but the end is not yet.

It is a great pity that we have not more men in here to prospect this winter. They would have good chances to benefit themselves and the country; but I have harped on this string until I am tired. We have not actually had more than two men in camp this year at all acquainted with quartz, outside of those who are now here. Along came a few broken miners looking for two or five dollar placer diggings. "They come like shadows and so depart," and through ignorance, and as a salve to their own minds, spread the report that the whole country is not worth a cent. I fear that the wish is father to the thought. If they had worked around and prospected, I could not blame them; but those to whom I allude never stooped a pick in the ground, and some never saw a prospect hole while they were here. Pecuniarily, it is a matter of the most perfect indifference to us whether we get a population or not. We know that it depends on ourselves to develop the camp, and if we have a good thing, we alone shall benefit by it; but the reason for this growl is that no miner likes to see his camp run down by those whose motives are dictated solely by envy and malice.

Cornucopia District.

A correspondent of the *Silver State*, writing from Cornucopia, says: That our camp is going to be one of the best on the coast next summer, there is no doubt. The Leopard shipped a little over \$85,000 last month. They shut down twenty-four hours for repairs, but are in successful operation now, and will probably continue so all winter, notwithstanding what the croakers may say. All we want is a good outlet during the year around.

I obtained some items the other day in relation to the Leopard mine from an old and experienced miner, Geo. W. Tucker, who informs me that the mine is prospected to the depth of 187 feet, and that in their tunnels, drifts, etc., they have at least one thousand tons of good ore in sight. The claim is bounded on the southwest by a change of formation from what it used to be, and they are now running south-east and northwest. It is bounded on the west by an iron formation.

The Hussey mine is located on the northwest end of the hill, and is now down to the depth of 347 feet, and develops a large body of ore bearing southeast. Along the line of the Leopard and Hussey comes in the Consolidated Cornucopia on the southeast, which bears the same character of ore as the Leopard and Hussey, and is worked to the depth of 116 feet, and is now in good sulphuretted ore, and everything proves the fact without doubt, that it is a good fissure vein. Other mines might be mentioned, but I defer it to some other time.

REPAIRING.—Everything in and about the Eberhardt & Aurora company's mill looks busy. The whole institution is undergoing general repairs, and when finished will be quite as good as an entire new mill. It will be recollected that the present mill was resurrected from the one that passed through the fire, and which has done admirable service during past year. We learn that all the old pans are to be replaced with new ones, and that extensive repairs will be made to the stamps. Perley Rowell is master of the situation, and has all the millwrights, machinists and blacksmiths at work that can be employed. He expects to have it running again in about three weeks.—*White Pine News*, Jan. 15th.

Big Blasts.

We noticed some months since, in an exchange, an account of a big blast doing splendid execution, consisting of seventeen kegs of powder, and we frequently observe statements of big blasts consisting of from fifty to one hundred kegs. Had the writers thereof added that they were big blasts for their districts, they probably would have told the truth.

A few days since we witnessed what to us was the largest blast we ever saw. It consisted of three hundred and fifteen kegs of powder, and to say that it was a big blast would not be doing Col. Ludlum, the superintendent of the Cedar Creek company, justice, for the reason that he only considers it a medium affair, not of sufficient importance even to let the citizens know when it was coming off, and we doubt if fifty persons knew that such a blast was being proposed, and many of the inhabitants of our little town will hear of it first through this article.

Should those parties who call seventeen kegs a big blast take the trouble to visit this district, Smartsville or You Bet, they will probably learn something of bank blasting.

The blast above referred to, as before stated, consisted of three hundred and fifteen kegs of powder, which were placed under a bank about one hundred feet in height and distributed in seven chambers cut into the hard cemented blue gravel; the powder was placed therein and the drifts leading to the chambers, all tamped solid with earth and boulders; Col. Ludlum always takes the precaution to place a string of fuse leading to each chamber of powder in addition to the electrical wires, which as he says assures success in case the wires are broken.

At the time agreed upon the labor of tamping up the drift, which had been going on for the previous thirty-six hours, was completed and it was announced that all was ready. The men appointed for the duty were instructed to light the fuse, which they obeyed, and on their return the command was given "ready," "fire," the party operating the electric battery gave twenty rapid turns at the right and half a turn to the left, at which instant all eyes that were centered on the spot witnessed the hill rise up about eight feet, an apparent shuddering of the immense body and the bank settled back crushed; nothing remained to exhibit the action of the instantaneous explosion or the 7,875 pounds of powder but the rising smoke and the crumbling mass of gravel.

To say that we were disappointed does not do justice to the subject, we were more than that; we were surprised that such a quantity of powder could be exploded so near to where we were standing and affect us so little; we expected at least to hear a terrible report, that the earth beneath us would shake, tremble, and that we should witness an upheaval of immense numbers of cobbles, but no such demonstration took place; to us it seemed like a tame affair until we approached the crumbled bank and realized what immense power was necessary to lift up and hurl down with crushing effect such an immense pile of gravel.

Parties familiar with such operations pronounce it a perfect success, and state that it has loosened material sufficient to keep the claim washing for at least a month to come. From the appearance of the bank we conclude that the gravel is rich, and notwithstanding the cost of this blast for labor and powder has exceeded two thousand dollars, the company will undoubtedly be remunerated for its outlay.—*Dutch Flat Forum*.

The Wagontown Mines.

The Idaho *Avalanche* says: From Mr. B. Wilbur, who was in town yesterday from the Wagontown mines we learn that Messrs. Peters, Ponlin, Oglesby and Warren have resumed operations on the Henrietta mine, and are now working a force of ten men. It is their intention to develop the mine with all possible dispatch and take out a large quantity of the rich ore for which it is famous.

The Maggie continues to show up splendidly. Four tons of ore were taken out the other day, which is very similar in quality to the rich ore extracted from the Henrietta last fall, and which yielded away up among the hundreds per ton. We understand that the Maggie will have steam hoisting works before long. This looks like business, and demonstrates the fact that the company are well satisfied in regard to the future prospects of their mine. The Maggie starts out under very favorable auspices.

Houses are in great demand and rents are very high in the district. A small house situated close to the Maggie and Henrietta mines rents for \$24 a week, and the most insignificant log cabin thereabouts is readily sought after at \$25 per month. Mine owners in general are jubilant over their prospects, and we confidently believe that within a period of eight months the new district will have a population of at least 1,000 people. Next summer several incorporated companies will be operating; quartz mills will be erected, and lively times will prevail.

LEAVES of the pine-apple, now being extensively cultivated in the East Indies, are turned to account by being converted into a kind of wadding, which is used for upholstering instead of hair. A sort of flannel is also manufactured from them, from which substantial waistcoats and shirts can be made.

MECHANICAL PROGRESS.

Glass Journal Boxes.

Within a comparatively recent period there has been commenced, by Messrs. Campbell, Jones & Co., the manufacture of glass journal boxes designed to supplant the brass boxes now in use. Proper molds have been made, and one pot of glass of a peculiar "mix" has been fashioned into the article. One car on the Citizens' passenger railway, Penn street, has been provided with these boxes, and the experience of seven days speaks very favorably for them. Other cars of the same line will soon be supplied, and meanwhile a car on the P. & B. line will be fitted up with the new boxes. The experiment was recently tried in one of our planing mills to use a glass box for the journal of a saw shaft, and the result was highly satisfactory. The common supposition is that the lack of friction would do away entirely with oil, but Mr. Jones, of the firm, advocates the use of a very small portion of lubricating fluid, as is much safer.

Several boxes have been submitted to the test of hydraulic pressure, and the following results obtained: A box made of ordinary glass sustained a pressure of ten thousand pounds to the square inch before cracking. A box made of the special "mix" required a pressure of twenty-seven thousand pounds to shatter it; so it is plain that the special "mix" is best. The mode of tempering, too, is slightly different from the plan commonly in use.

Although the idea of making glass journal boxes is not a new one, yet this is the first instance of their being successfully made. Messrs. Campbell, Jones & Co. have had assigned to them the rights of an inventor of glass slide bearings, and with their own patent rights possess a clear field in the market. We have just seen an experimental machine at their glass works, the shaft of which has seven hundred and seventy-two revolutions to the minute. It had been running for four hours continuously, and both the boxes and shaft were perfectly cool.—*Pittsburg Herald*.

A NEW SPARK ARRESTER.—Mr. Wm. Stamp, a machinist employed in the Erie railway shop in Susquehanna, Pa., has patented an improved invention for preventing sparks and cinders from flying out of the smoke stack of a locomotive. His exhaust has a spiral channel connecting with a similar channel in the smoke stack, giving the cinders a centrifugal force that sends them against the inside of the stack, whence they are conducted to the ground. They can be retained if necessary, and deposited at any point along the railway. If this invention can be made practicable, it is calculated that locomotives can burn with less coal, and passengers can raise the windows without having their eyes filled with cinders or soiling their clothes. The engineer can keep a better lookout, and the cars may be thoroughly ventilated without annoyance. So sanguine is Mr. Stamp of the success of his invention that he offers to give two stacks to any company having more than ten locomotives, and pay all expenses if the result is not satisfactory. Any company having twenty-five locomotives can have patterns to build four stacks, a company with fifty can have ten, and a company owning two hundred locomotives can build twenty stacks free of charge for patents, if built within six months.

AN IRON CARRIAGE WHEEL.—A new principle in the construction of carriage wheels has been brought to notice by an English inventor—every part of the same consisting of wrought iron, with the exception of the tire, which is formed of the best cast steel. The method of fastening the spokes—which are hollow—both in the rim and in the boss, is such, it is claimed, as to insure safety by the simplest means. The tire is so constructed as to protect the other parts of the wheel when it runs against the carstone, or comes in contact with another vehicle. Neither in patting on the tire, nor indeed any portion of the work, is a single bolt or nail employed, the spokes being clipped into their places in the rim and boss, and afterward locked up by a nut, while the tire is firmly inserted into a groove in the rim. The strength of the axle-tree is increased at the points where it is most liable to give way, and the boss is made to accommodate about four times the usual quantity of oil for lubricating purposes. Although made of iron and steel, the wheel is not more than two or three pounds heavier than the ordinary kind.

COIL BOILERS, or steam generators formed of one continuous coil of iron pipe, are coming into use again to some extent, although they are by no means new. They are used for small powers, for steam launches, and for stationary purposes, and make a cheap and, for the time being, serviceable evaporator.

CASE-HARDENING IRON.—A simple method of case-hardening iron is to sprinkle powdered prussiate of potash over it at a red heat, and plunge it into water; bichromate of potash with the pith of ram's horn may be used, with good results, instead of the prussiate.

Magnetic Separation of Iron and Steel.

Some time ago we called attention to certain machines which were employed on the river St. Lawrence, in Canada, for concentrating by means of magnetism the ferruginous sands so abundant in those parts, and in which the iron existed in the state of the native magnetic oxide of this metal; we now call attention to a somewhat similar arrangement called a magneto-mechanical separator, which has for its object the separation of iron and steel filings from the copper, brass and other filings which accumulate in the workshops. The machine is the invention of Mr. Charles Vavin, and was described by M. Bonillet at the meeting of the 1st May of the Societe d'Encouragement des Arts, etc. We must refer to the original source for details, but it may be mentioned that the mixed filings fall on two cylinders placed one above the other, and furnished with rings of soft iron, which are rendered magnetic by strong artificial horse-shoe magnets of iron, placed as radii. Effective arrangements are made in order to render active the entire surface of the cylinders, and a brush of pig's bristles detaches the adherent filings. It is stated that the separation proceeds very well, and that a machine not costing more than £50 is capable of cleaning half a ton of filings per day. Judging from the description, however, we should be inclined to give preference to the machine used at Quebec, which has already been noticed in a former report.—*Iron Age*.

SOMETHING NEW IN BOILER FLUES.—The National tube works company, of McKeesport, Pa., says the *Times*, are now manufacturing wrought iron lap-welded tubes in all sizes up to fifteen inches diameter, the larger of which are now being adopted on our steamboats for boiler flues, instead of the riveted flues, and a large number of steamers are now using them. These tubes are giving satisfaction, and the local inspector at Cincinnati says they have proven themselves all that could be desired. There are many advantages claimed for these tubes as flues, among which we might mention the following: They are cylindrical in form, a point not claimed for the riveted flue, thereby lessening the chances of collapsing, if not absolutely preventing accidents of this kind. There are no rivet heads or laps to interfere with the draft, and consequently the flues are not liable to choke up with soot, are much less apt to scale, and, having a smooth unbroken surface, are of course much more easily cleaned, a fact that will be appreciated by the firemen. Another point claimed is that they are of uniform gauge, having no rivets or laps, and must naturally require much less fuel, a fact that will undoubtedly receive due consideration.

THE LARGEST GLASS CYLINDER IN THE WORLD. Mr. Thomas Degnan, of the Union glass works, in Somerville, Mass., recently made an enormous glass cylindrical shade or cover for a statue which is to be exhibited at the Centennial. The process began by inserting a long hollow iron tube into the pot of molten glass, and by careful manipulation about 75 lbs. of the latter was caused to adhere to the tube. This was then taken to a wooden mold of semi-circular form, in which it was rolled a few times by three men, and thus brought to a white heat. It was then taken to a wooden cylinder placed beneath the floor of the factory; and after it was placed therein, Mr. Degnan began the work of fashioning the cylinder to its proper proportion, which he did by blowing through the iron tube and into the body of the glass; while at the same time, two men, guided by a wave of his hand, raised and lowered the glowing cylinder gently but quickly until it came forth finished, and measured 5 feet in height and 74 inches in circumference.

NEW MODE OF RAIL CONSTRUCTION.—An American rail manufacturer prepares rails partly in steel and partly in iron, by grooving a bar of iron to a good depth on its sides, and placing the bar, at a proper heat, in the ingot mold, upon the liquid steel which has been run into it. A perfect weld is obtained, and the bar is rolled by the usual process.

INDUSTRIAL progress appears to be interminable; the first step of conceiving labor-saving machinery was only a beginning, as, not content with this, the inventive genius of our practical men cannot rest, but is continually improving on existing machinery; hence the improved contrivances of different kinds which come continually under our notice.

STEEL SHIPS.—The British Admiralty having decided upon the construction of two dispatch vessels to be made entirely of steel, the order for the plates and bars for the same has been given to the Landore Siemens steel company, of Swansea, who undertake to supply a very mild steel of high quality. These vessels will be built at Pembroke dockyard.

SOFTENING CASTINGS.—Place the casting, surrounded by sawdust, in an iron box; close it up with clay, to exclude the air, and subject it to a red heat for several hours; the castings must be cold before they are withdrawn.

SCIENTIFIC PROGRESS.

The Uses of Ozone.

Our readers are, no doubt, generally familiar with the chemical nature of ozone, and with the modes of preparing it for chemical purposes, by electrical action upon atmospheric air. Ozone, it will be borne in mind, is merely a modification of oxygen, just as plum-bago is one modification of carbon while the diamond is another. Ozone differs from ordinary oxygen, in the fact that it is far more energetic in its action—oxidizing rapidly metals and other substances which are effected by oxygen only after long exposure. Its specific gravity is one half greater than common oxygen. It possesses a most marked odor, while oxygen is odorless. This odor is easily recognized in the atmosphere, during and immediately after a severe thunder storm. It is a slightly sulphurous smell. It is this characteristic which gives it the name ozone, from *ozein*, a Greek word, meaning to smell.

From a mere laboratory curiosity ozone has now become largely employed in medical practice and in the arts; and its use would be rapidly increased if some means could be devised for producing it cheaply and on a large scale. Various processes for its manufacture have already been patented in Europe; but as yet none appear to have any practical value.

Lender has established a manufactory for ozone in Germany, and ozone inhalations may be had for about twenty cents per cubic foot of the gas. Ozonized matter is also sold for twenty-five cents per bottle.

The first patent for the application of ozone to manufacturing purposes was recently granted in England. Under this patent acetic acid is formed from alcohol without fermentation. The ozone is obtained by blowing air through a flame and bringing it in contact with a current of alcohol. Whether the experiment will prove a practical success remains to be seen.

Cheap ozone might be largely employed for bleaching purposes. Grass bleaching is due to the presence of ozone in the atmosphere. In its nascent state, as produced by electricity during thunder storms, ozone oxidizes the nitrogen of the atmosphere, and we have nitric acid. It is from this source that rain water, which falls during a thunder storm, derives its large proportion of nitric acid.

The nitric acid of commerce is obtained from niter; but if ozone could be economically produced, it could doubtless be employed for preparing that acid by synthesis—as nature produces it.

Ozone has also been recommended as a disinfecting agent for the sick room, and various methods of generating it for this purpose have been proposed. One, which is commended for its simplicity, is by means of a mixture of the permanganate of potash and oxalic acid. Two spoonfuls of this in powder, moistened with double the quantity of water, a little more water being added every two hours, will emit ozone freely. Another method, even simpler, which is said to work well, is to dip a bunch or part of a bunch of common friction matches into water until they are thoroughly moistened, and then to expose them to the air in the room to be disinfected.

DOES SUNSHINE PUT OUT A FIRE?—A good deal of discussion has lately taken place in this country over the old question whether sunshine checks combustion. It is an old notion that sunshine lessens the intensity of a fire, and may even put it out, and the theory was that the sun's heat by expanding the air caused a diminished supply of oxygen to the coal. This and all other explanations are condemned and the fact is denied. One writer says that if a few pieces of charcoal are ignited in a chaffier, and placed in a sunny room provided with closely fitting shutters, the fire will appear to die away in the sun's light. But if the shutters are closed, the coal will be seen to be in full combustion. There is no phenomenon at all, but only the appearance of one, which is due not to the sun's heat, but to the fact that its light, being stronger than that of the coals, overcomes and subdues it. The fact of combustion is so intimately connected with glowing ignition in our minds, that anything which lessens the glow appears also to diminish the combustion.—*Cassell's Magazine*.

SCIENTIFIC SURVEYS.—The Secretary of the Interior, in his annual report, says: "The results of the geological and geographical survey of the Territories, conducted during the past session by Messrs. Hayden and Powell, under the direction of this department, will, it is believed, equal in interest and importance those of any previous year. The survey under F. V. Hayden continued its labors of the two preceding years in the Territory of Colorado. The survey of the southern and southwestern portions of Colorado has been completed. The total area surveyed was about 30,000 square miles, portions of which were rugged. The explorations of the remarkable pre-historic ruins of Southern Colorado, glimpses of which were obtained the preceding season, was continued with great success. The survey under J. W. Powell continued the labors of the preceding year in the Territory of Utah. Nearly 10,000 square miles of country were surveyed during the season just closed.

A New Explosive Copper Compound.

The dangerously explosive character of acetylen copper is well known. Many serious accidents have occurred from its presence—spontaneously formed—on copper pipes employed for conveying illuminating gas. Such accidents have resulted from slight blows with a hammer or some other iron tool given by workmen when engaged in making repairs, etc.

According to a German scientific journal, the *Polytechnisches Notizblatt*, another copper compound has recently been prepared, which, when mixed with chlorate of potash, forms an explosive, which it is proposed to use for filling percussion caps, torpedoes, etc.

The mode of producing this compound or salts of copper is as follows: To a solution of sulphite of copper is added enough hyposulphite of soda, in solution, to entirely destroy the blue color. To another portion of the blue vitriol solution, aqua ammonia is added, until the blue precipitate, at first formed, dissolves to a dark blue solution of ammonia—oxide of copper. The two solutions are now mixed; and after long standing, a violet colored salt crystallizes out of the beautiful blue liquor. It is this salt which becomes explosive when mixed with chlorate of potash.

The composition of the "violet colored salt" above referred to, and which constitutes the new explosive, is not given by the authority quoted; neither is any reference made to the probable cause of its explosive nature. It may possibly be due to the nitrogen imparted to it by the ammonia; or by a large proportion of sulphur which may be present, which latter substance, when in a free state, forms with chlorate of potash a mixture that detonates by percussion.

SCIENCE AND THE ARTS.—The Gramme electric machine promises to become one of the most valuable discoveries of modern times. This machine is now under the control of Mr. Werderman, of London, by whom it is gradually but surely being introduced into practical use, and bids fair to work quite a revolution in several important branches of industry. The greatest electro-plating house in the world, Christoffe & Co., of Paris, use ten of these machines, and no others. It is claimed that by its use aluminium may be made on a large scale, and at but a moiety of its present cost. Potassium, sodium, magnesium and caustic soda can be produced at a fraction of their present cost. Of its ultimate employment for telegraphing and general use for light-houses there can be but little doubt. But it is asserted that one of its most profitable uses will eventually be the reduction of refractory ores, such as sulphurets of gold and silver. And it is also hoped that it may yet be profitably applied to the reduction of iron ores. Iron may be produced quite free from sulphur, phosphorus and other impurities, so that steel may be produced directly from the smelting furnace.

THE NEW INVESTIGATIONS IN MAGNETISM.—MM. Treves and Durassier have recently investigated the question of whether, and how, in a steel magnet, the known portative force varies when the weight and section are affected by the gradual dissolution of the magnet in an acid. The result is that the force is always proportional to the section and to the weight, so that a curve representing the variation of weight and section would be parallel to one indicating the diminution of intensity. As the dissolution progresses, the metal shows serrated inequalities perpendicular to the axis of the bar; and if a horse-shoe magnet be treated the curved part is found to dissolve incomparably quicker than the straight portions.

THE ELECTRIC LIGHT has recently been applied for lighting the mills belonging to Messrs. Heilmann, Ducommun & Steinlein, in Muhlhausen. In a separate room four magneto-electric machines are placed, which feed four suitably located lamps constructed on the Serrin principle. The dimensions of the room are 196x98 feet. Each lamp gives a light equal to about 100 Carcel lamps. Each magneto-electric machine requires about 360 foot-pound motive power. The cost of the lamps, exclusive of the maintenance of the motive power, averages about 20 cts. per hour. The magneto-electric machines have each cost \$300, the whole arrangement amounting to 1,600.—*Electrical News*.

WATERPROOF TISSUES AND PAPER.—*Les Mondes* say that bichromate of potassa has the property of rendering gline and gelatin insoluble in water. Thus paper, and stuffs of cotton, linen, or silk, if once coated with this insoluble gline, become perfectly impervious. To render gline insoluble, it is sufficient to add to the water in which it is dissolved, one part of bichromate to fifty parts of gelatin. The addition is only made at the moment when the liquid is to be used. The process is conducted in full daylight. The Japanese make their umbrellas with paper prepared in this manner.

INTERESTING OPTICAL EXPERIMENT.—Prof. F. E. Nipher sends to *Nature* the following pretty optical experiment. Observe a white cloud through a plate of red glass with one eye, and through green glass with the other eye. After some moments transfer both eyes to the red glass, opening and closing each eye alternately. The strengthening of the red color in the eye, fatigued by its complementary green, is very striking. Many modifications of the experiment will readily suggest themselves.

and nuggets of gold worth \$5 and \$6 each are found scattered through the boxes, while coarse gold is visible almost anywhere in the bottom of the sluices. The owners are sanguine of securing an amount of gold at the next clean-up sufficient to leave a handsome margin after defraying all expenses. Traeb & Belliard, who are working the adjoining claim, known as the Montreal mine, are within a few hours' work of the principal auriferous channel.

CALAVERAS.

EXTREMELY RICH ORE.—Calaveras Chronicle, Jan. 22: We learn that rock of unprecedented richness has been struck in a mine at Mosquito gulch, owned by Messrs. Clark & Langdon, of Stockton. Our informant states that the quartz being extracted is fairly flecked with gold—absolutely permeated with the precious metal. We have heard no estimate of the probable yield per ton, but unquestionably it will be enormous.

REMARKABLE YIELD OF GOLD.—Again we have to chronicle a remarkable yield from the Champion quartz mine, at West Point, owned by Messrs. Haskins & Hadley. Forty-seven tons of ore taken from the Champion yielded up wards of \$5,000—an average of nearly \$110 per ton! For unsorted rock such a product is almost unprecedented, certainly not exceeded, if equaled, by any other mine in the State. It is a notable fact, one scarcely paralleled in the history of the quartz mining operations, that all the rock taken from the Champion, from the commencement of work upon the lead down to the present time, has paid over \$100 per ton—some of it as high as \$180. The bullion taken from the mine was melted and assayed by Mr. C. Schlund, of this place.

INYO.

ECLIPSE.—Inyo Independent, Jan. 15: After putting through 180 tons of average ore, the mill made a general clean-up a few days since, and we are very much pleased to be able to say, with quite satisfactory results. As was perfectly well known in advance the ore is low grade, and consequently the margin for profits per ton could not be large. As an actual fact this clean up shows a clear profit of \$2 per ton, which, small though it is as compared to some mines, is yet the most promising and important mining success, mill process, that has yet been made in this county, perhaps without a single exception, although ores have been worked, each ton showing nearly as much profit as these 180 combined. But this success indicates what can, and sooner or later will be done upon hundreds of low grade mines which otherwise would remain untouched. The Messrs. Endeys have, in this, demonstrated what judgment and economical management can do, and in doing it have accomplished more of real promise for Inyo mining interests than any others in this particular branch of mining that we know of. The working value of this ore was \$10 per ton. We do not know the percentage of loss, but as this was the first run and necessary appliances by no means full or completed, it was doubtless somewhat larger than it need be hereafter. Instead of twenty stamps thirty will be put to work, and with everything as intended it is quite likely the same class of ore will be made to yield about double the profit it did this first run.

GOON ORE.—Coso Mining News, Jan. 22: We mentioned last week that S. Lillien had shipped from his mine in Lookout district some ore to the Sunrise mill for reduction. Parties in from Lookout now inform us that the ore (2,100 pounds) worked in the mill \$839.41. The report is also corroborated by Dr. F. T. Bicknell and James Bruce, who came in from Panamint last Monday. We think this pretty good for silver mines, but we are not averse to publishing a better report if anybody can make as good a showing.

COSO ITEMS.—Defiance furnace has been running constantly since our last issue, without the least interruption; in fact there has not been a stoppage since the 22d of December last. The company has shipped since last Wednesday evening 1,360 bars of bullion, average weight 86 pounds to the bar. Shipments are now daily being made on the teams of the Cerro Gordo freighting company. Indeed, the Defiance is furnishing about all the freighting out that this company receives.

The Cervo furnace started up on Monday morning last, and they have succeeded in turning out quite a number of bars of bullion, still it is not working perfectly as yet.

LEE DISTRICT.—From G. M. Jordan, recorder for Lee district, and who came in last Tuesday, we learn that the wagon road from the Emigrant company's mines will be completed in the next three days, so that the machinery for their ten-stamp mill, which is now on the way, can be gotten down to the site prepared for it. The grading for the mill is all done, and as the frame and other timbers for same were made below and are being transported here with the machinery, there is no doubt but that the mill will be running in three or four weeks.

PANAMINT ITEMS.—From Dr. Bicknell, who came in from Panamint last Tuesday, we have the following items: The town itself, although yet a little dull, is gradually but surely improving. The S. V. M. & W. Co.'s mill is kept running night and day, and crushing custom ore when offered. On the Hemlock mine sinking is being vigorously prosecuted; they have attained a depth of about 400 feet, and the splendid, smooth foot-wall, of which we had occasion to speak so often in the Panamint News, and which we predicted would go to a great depth, is still seen at this depth, and an increased body of ore is found and of higher grade. The Sunrise mill is also running there

usual number of hours, and is doing quite well. Developments are still being made in their mines which justify the expectations of the owners at the commencement.

KERN.

GRANITE ITEMS.—Cor. Kern County Courier: Granite is the new postoffice which has been established but a short time, and is northeast from the county seat; distance, about twenty-five miles from said point. There have been several valuable discoveries made in this vicinity in the past, and also within the last six months, in the way of quartz lodes, containing gold and silver. The Loag Tom miniag district heads the list; here there are two very valuable gold lodes, the first known as the old Long Tom, owned at the present time by Col. Burdett, and the second by Wm. Youkum. These two mines have yielded something over two hundred thousand dollars in the past ten years, and are capable of doing even better at the present time, if properly worked. There is a ten-stamp mill on the Burnett mine, but owing to some case of litigation in regard to the mine and mill, work has been suspended for an indefinite length of time. About one mile north of Long Tom is situated the Eagle mine, owned by David Engle and J. Higgins. This mine is very rich in free gold. The ledge is from eight to fourteen inches in width, and yields from sixty to eighty dollars per ton, and pays well to assay. The owners have been at work for the past four months, assaying and opening up the mine. Five miles farther north and two miles northeast of Granite station we come to the Harbut mine, situated in Harbut mining district, and located in September, 1875, by C. M. Harbut, formerly of Yolo county, California, and present owner of Granite station. This mine bids fair at the present time to become one of the leading mines in Southern California, as it works from twenty-seven to thirty dollars per ton in gold by mill process. The main shaft is over eighty feet in depth from the surface. The ledge at that depth measures over seven feet in width and the ore is uniform as regards the pay per ton. This mine has every advantage as regards location, as there is an abundance of wood in this district, and a fine water power for mill purposes. Work will be resumed at the mine about the 20th of this month. I understand that the owners intend to sink to the depth of one hundred feet and then run an incline each way from the main shaft, preparatory to erecting a quartz mill.

PLACER.

CLEAN-UP.—Dutch Flat Forum, Jan. 22: We are in receipt of information that Messrs. Tebbetts & Chapman cleaned up one joy last week \$3,000 from twelve days' "run." The claim from which they have deducted the immense yield is located on the "Blue lead" at Little York. The process of reduction was somewhat tedious, it being necessary to run a powder-drift and sink a shaft in order to enable the operators to convulse the gravel by powder explosions.

SAN BENITO.

A NEW STRIKE.—Hollister Enterprise, Jan. 22: Our old friend, Bob Stayton, still continues to unearth new treasures in the Stayton quick-silver mine. A rich strike was made in the Yellow Jacket tunnel on Tuesday, which proves beyond cavil or doubt that the mine is not only rich but extensive. The vein in the old tunnel is eight feet wide—solid, first class metal—and for the purpose of testing its extent, a new tunnel was started on a perpendicular line several feet below, in which the lode was tapped as stated. Thirty wheelbarrows of high grade ore were thrown out by one blast. The mine has lately been sold to an English company for \$250,000, and evidences have been accumulating that they have got hold of a valuable property. It is now clear that this locality, which embraces the Stayton, Consolidated Wonder and other mines, is destined to be the second New Almaden of the State.

SAN BERNARDINO.

BEAR VALLEY MINES.—San Bernardino Argus, Jan. 15: Col. Chipley, the gentleman who bought in the Gold Mountain mining company's mill, situated at Bear valley, informed us before he left that it was his intention to organize a new company, put the mine under different management, and thoroughly prospect the claim. As the colonel is a man of energy and considerable influence in San Francisco, we prophesy that before two months more pass away, the sound of the hammer may again be heard at Bear valley. It seems to be generally conceded by those living at the mines and working in the employ of the company, that from first to last it has been a freeze-out game, inaugurated by Baldwin and the rest of his followers. Those poor people who had any stock in the mine were froze out in a barefaced manner; assessment after assessment was levied, and it would take a Philadelphia lawyer to find out where the money was expended.

Nevada.

WASHOE DISTRICT.

OPHIR.—Gold Hill News, Jan. 20: The machinery, both hoisting and pumping, is working finely. The repairs to the drifts on the lower levels are making excellent progress. Ore is now being regularly hoisted. The Nevada mill was started up yesterday morning. The work of opening an additional compartment at the north end of the shaft was also begun yesterday morning. Work was commenced both at

the top and bottom of the shaft. In a short time openings will probably be made at several intermediate points and the construction of the new compartment pushed to completion as rapidly as possible. The long gallery connecting the hoisting works with the east ore house is completed.

OVERMAN.—The north drift on the 1100-ft level is pushed steadily ahead, to connect with the south drift from the bottom of the winze on the same level. These drifts have only twelve or fifteen feet yet to run to complete the connection. This connection will ventilate the 1100-ft level and permit the cross-cutting of the ledge in that portion of the mine, if so desired. The pump station on the 700-ft level is being enlarged, so as to admit of a much heavier pump bob.

CHOLLAR POTOSI.—Daily yield fifty-five tons of ore. There is no change whatever in the ore-producing stations of the mine, and the decrease of the daily yield is caused alone by the inability of the teams to haul the ore to the mills as fast as it is extracted.

SILVER HILL.—A strong flow of water was encountered during the first part of the week in the east drift on the fourth station level. The water has checked again somewhat, and the pumps now have it under good control. This water is a strong evidence that the main ledge is not far away, and once the body is drained so that the development can proceed, some good results are looked for.

IMPERIAL-EMPIRE.—Owing to the bad roads and the inability of the teamsters to get the ore to the mills, but a small amount of the ore has been extracted during the past week. The dumps are still full, and only enough can be extracted to supply the space of the very small portion delivered at the mills.

CALEDONIA.—Sinking the main shaft is making good progress, notwithstanding a strong flow of water has been encountered in the bottom.

JULIA.—The drift on the 1600-ft level is in a distance of 56 ft, the face showing some very favorable prospects. The face of the main south drift, on the 1400-ft level, is almost entirely in fine quartz and ore.

CONS. VIRGINIA.—Daily yield, 550 tons of ore. The mills are kept steadily running on ore from the mine, and had it not been for the breakage of a spur wheel the California mill would ere this have added nearly 300 tons per day to the crushing capacity of the company. The ore breasts and stopes are all yielding splendidly, the north drift on the 1500-ft level of the California having reached the north line and connected with the Ophir. This drift is run its entire length in good ore. The north drift on the 1500-ft level is still pushed vigorously ahead to connect with winze No. 5, which is about 200 ft south of the Ophir line. The face of this drift is also in rich ore. The east drift on the 1500-ft level, running to connect with the O. & C. shaft on the 1350-ft level, is making good progress.

CALIFORNIA.—Sinking the O. & C. shaft is making excellent headway, the bottom being in good working ground. The main north drift on the 1500-ft level has penetrated to the Ophir line, the entire distance in good ore. The north drift on the 1550-ft level is steadily advancing, to connect with the winze sinking in cross-cut No. 5, the face of which is in rich ore.

LADY BRYAN.—Sinking the main shaft has made slow progress during the past week, owing to a steady and strong flow of water, which has been about all that the pumps could handle. The ore in the shaft continues of a good quality. The ore in the north drift on the 380-ft level is also holding out finely. The west cross-cut at the shaft, on the 380-ft level, is showing some fine ore. An average assay of all the ore bodies in the mine, made a few days since, gave \$47.50 per ton, a pretty good showing.

SIERRA NEVADA.—Sinking the new shaft goes steadily forward. The main south drift on the 1250-ft level is making good progress, the face in soft working ground. The main south drift on the 1000-ft level is also making fair progress, the rock in the face being a little harder than for some time past.

SILVER CITY.—Good practical work is being done in this mine, not only in the way of prospecting exploration, but ore extraction. The stopes and breasts above the adit level are showing an extensive amount of ore, and are being very systematically worked. The ore is selected with care, and a good large pile is accumulated on the dump.

SUCCOR.—The face of the main west drift on the 550-ft level is in hard blasting rock. The north cross-cut from this drift cut during the week a fine streak of white quartz 18 inches in thickness.

SAVAOE.—Cross-cutting and drifting on the 2000-ft level has been resumed. Repairing the drifts and winzes on the 2200-ft level is making steady headway, the damage to the drifts by the water being much greater than was at first supposed.

SULLIVAN.—South drift in 68 ft; vein formation hard. A cross-cut east has been started from it to go for the east wall and develop what can be found in that direction. Owing to the impracticable state of the road to the mine the requisite timbers for the shaft cannot be supplied at present without extra cost. For this reason the sinking of the shaft deeper will be deferred for a short time, and meantime explorations of the present level proceeded with. The vein matter is fully 180 ft between walls, and is of the regular white ore, Comstock character. It is the strongest, best and most promising fissure we have yet seen in that sec-

tion of the east range of the great Comstock belt.

DATTON.—The main shaft is now down 608 ft. A new set of station timbers has been put in at the 600-ft level, and the sinking is again proceeding. The main south drift on the 300-ft level is in a distance of 433 ft, and is making good progress toward the Kossuth north line.

KOSSUTH.—The main south drift on the 350-ft level is steadily advancing to the southward, the face in white quartz of a much softer and more favorable character than any yet encountered in that portion of the mine.

NORTH CONS. VIRGINIA.—Sinking the shaft for pump room below the 630-ft level, preparatory to opening a station and drifting for the ore vein, is nearly completed. The streaks of quartz in the bottom of the shaft are showing better.

LADY WASHINGTON.—Cattag out for a tank at the 530-ft station for the second plunger of the pump. The whole bottom is now in regular white Comstock vein matter of the most promising character, with streaks of quartz which give low assay.

PICTOU.—Total length of tunnel, 1,176 ft. The company now propose sinking a winze shortly in the front ledge passed through lately, which had five feet of clay wall and ten feet of ledge matter.

JUSTICE.—Material in face of south drift, at the 1000-ft level, somewhat softer. Face of drift at 800-ft level in porphyry, clay and quartz, giving low assay. Ore breasts and stopes at the 400 and 600 ft levels yielding as usual.

ORIGINAL GOLD HILL.—The raise above the south ore body is in excellent ore, and showing finely. The ore breasts and stopes are yielding as usual, about 20 tons daily. Hauling and milling will be resumed shortly. Splendid assays have been obtained during the past week.

SUREO TUNNEL.—Some very good streaks of low grade ore have been passed through at late, and the prospects for running into a bonanza are not bad by any means. An assay office has been erected near the mouth of the tunnel. Total length of tunnel last evening, 11,983 ft.

BEST AND BELCHER.—The mine will resume full operations on the lower levels as soon as the retimbering of the Gould & Curry shaft is completed and the water drained down to the 1700-ft level.

SOUTH COMSTOCK.—Cross-cut in 335 ft. It has passed through the hard streak entirely, and the whole face is in vein material of a very favorable character, with streaks of low grade ore.

NEW YORK CON.—The east and west prospecting drifts, on the 800-ft level, are both showing finely.

GOULD & CURRY.—Retimbering the main shaft is being pushed to completion with all the energy possible. The water has been drained down to the 1700-ft level.

COSMOPOLITAN.—Good prospecting work being done with some better ore in face of north drift.

UNION CONSOLIDATED.—The face of the south drift in the upper tunnel level is in a very favorable formation, and it is confidently expected that it will soon be the medium of some excellent developments.

EUROPA.—The north and south branches of the west drift on the 320-ft level are advancing steadily. The face of each is showing considerable quartz, and small seams of ore, mixed with porphyry.

CROWN POINT.—Daily yield, 425 tons of ore. There is little or no change in any of the ore producing sections of the mine.

BELOHER.—Daily yield, 450 tons of ore, keeping the mills all running up to their full capacity. The mine is looking well throughout, and the yield for the present month will fully equal that of December. Prospecting the 1600 ft level is going steadily forward, and the prospects have not been more encouraging for many months past than at the present.

YELLOW JACKET.—The north drift from the bottom of the north winze, on the 1940-ft level, is advancing in very favorable ground.

AMAZON AND GLASCOCK.—The station is opened at the 429-ft level and a drift started for the ledge. This drift is now in 30 ft, the face in ledge matter of a fine character. It cannot have very much farther to reach the principal ore vein. When the ledge is out some good ore developments may be looked for.

LEO.—A cross-cut west from the drift, at the bottom of the winze, is being run nearly opposite the east cross-cut. This drift is still in ledge material and ore. The ledge at this point has been opened a width of 40 ft without yet reaching the west wall.

HALE & NORROSS.—The work in this mine is mostly confined for the present to sinking the north and south winzes below the 2200-ft level.

GLOBE CONSOLIDATED.—The new ore discovery in the old upper works is looking finely, and strong hopes are entertained that the Globe will soon be a producing mine.

MINT.—The shaft has reached the 1000-ft level, at which point the sinking has been temporarily suspended for the purpose of putting a ladder-way and stations to the pump shaft.

BALTIMORE AND AMERICAN FLAT.—Pitting in the heavy pumps and columns, so as to be prepared in case a strong flow of water is encountered, is making good progress.

BULLION.—The combination drift northeast on the 2000-ft level is making good headway, the rock in the face being much softer than for some time past.

UTAH.—The new hoisting and pumping machinery will be started into full operation in three or four days more.

The California Mine.

We make the following extracts from the annual reports of the officers of the California mine, from the bonanza of which so much is expected this year.

The Superintendent says: During the past year the mine has been prosecuted as follows: On the 1300-ft level a drift has been run from our southern to our northern boundary, west of the ore vein, connecting with the openings of the Ophir mine. Cross-cut No. 1 has been run east 213 feet on the southern boundary to the ore vein. This drift has been extended north in the ore vein 100 feet, connecting with the winzes sunk in the ore body to the 1400-ft level. The ore found thus far on this (1300-ft) level has been of moderate quality, but that found in sinking the winze has been good from level to level.

On the 1400-ft level a drift has been run west of the ore vein the whole length of the mine, connecting with the Ophir mine on the north. Cross-cuts Nos. 1, 2 and 3 have also been extended from this drift across the ore vein. A lateral drift has also been run north from our southern boundary in the ore vein five hundred and sixty feet, and will soon be connected with the workings of the Ophir mine. A large amount of valuable ore is already developed on this level, but it is less regular than on the levels below.

On the 1500-ft level, a drift has been run from our southern to our northern boundary, west of the ore vein. Cross-cuts have been run from this drift one hundred feet apart, making six in all. The ore thus developed shows a width of from seventy-five to two hundred and eight feet. Cross-cuts Nos. 1 and 2 have crossed the ore vein. Cross-cuts Nos. 3, 4, 5 and 6 have not yet been extended across the ore vein, and its width is yet unknown. A lateral drift has been

Run in the Ore Vein

From the southern to the northern boundary, crossing all these cross-cuts and intercepting the openings of the Ophir mine. The ore passed through the entire length of this drift, except the northern 70 feet, has been of exceedingly high grade, assaying for weeks, during its construction, a thousand dollars (\$1,000) per ton. Three double winzes have been raised in the ore body from this level in cross-cuts Nos. 1, 2 and 3 to the 1400-ft level, all passing through ore of excellent quality. Four winzes have also been sunk from the lateral drift in cross-cuts Nos. 1, 2, 3 and 5 to the 1550-ft level, all of them passing through ore of high grade the whole distance. The developments on this level disclose a very large amount of exceedingly rich ore.

On the 1550-ft level the main drift has been extended north 400 feet from our southern boundary to cross-cut No. 5 in the ore body, passing through exceedingly rich ore, and the face of this drift is yet in ore of this quality. The main drift intersects all of the winzes sunk from the 1500-ft level. In cross-cut No. 1 the ore body has been developed to a width of 130 feet, and the ore vein is not yet crossed. Cross-cut No. 3 has been extended 65 feet, and neither east nor west walls have yet been reached. Cross-cut No. 5 has been developed 75 feet, and both ends of the drift are in high grade ore, as neither the east nor west walls have been reached. Between cross-cuts Nos. 2 and 3 a double winze has been sunk to the depth of 128 feet through ore of excellent quality the entire distance, and terminates in

Ore of the Same Richness.

Another winze has been sunk 320 feet south of our southern boundary to a depth of 147 feet. No cross-outs have been run from the bottom of these winzes. The developments made by these winzes prove the continuity at these lower depths of the same ore body which exists on the levels above, with an appreciation in the quality of the ore, which must be of great width. The sinking of these winzes has been temporarily discontinued on account of the increase of water and our limited means of hoisting. This difficulty will soon be obviated by the drift that is being run on the 1700-foot level of the Consolidated Virginia mine. This level is but partially explored. The ore found is of better quality than that on the levels above, and I have no doubt but that the ore body is of much greater width.

My efforts the past year have been to open the mine as thoroughly as possible on all the levels, and at the same time to take out as little ore as possible. The ore thus removed (5,123 4-5 tons,) has been daily hoisted, weighed, assayed and passed to our credit by the Consolidated Virginia mine, we not then having the mills to reduce it.

All of our levels are connected with the Consolidated Virginia mine on the south and with the Ophir mine on the north; also by the various winzes referred to, which thoroughly ventilate the mine and make it cool and pleasant. At the C. & C. shaft

Buildings Complete in Every Respect

Have been erected, and machinery for pumping and hoisting has been put in place and is now in full operation. In addition to the main building there is a blacksmith shop, a rope house, two large carpenter shops and one machine shop. The carpenter shops are supplied each with an engine and machinery—one of these shops being intended for the use of the Consolidated Virginia mine and the other for the California mine. The machine shop is fitted up with engine, lathes, tools, etc., one side of which is for the use of the Consolidated Virginia mine and the other side for the California

mine. For security against all fires the works are surrounded by hydrants, with a good supply of hose, and there is an ample supply of water under a very heavy pressure.

A large area of ground immediately surrounding the site of this shaft has been secured, having been purchased at a heavy outlay. This shaft is situated 1,040 feet east of the Consolidated Virginia shaft. It is now sunk with three compartments to the depth of 988 feet. The cost of this joint shaft to January 1st, 1875, was \$436,183.13. A drift is now being run east from the 1500-ft level of this mine, which will connect with the C. & C. shaft. It will reach that shaft and be

In Readiness for the Transportation of Ore

As soon as the shaft is sunk to that depth. Two hundred and eighty-eight feet remain to be sunk to reach this drift.

After this connection is made with the C. & C. shaft I feel safe in saying that our hoisting capacity will be 2,000 tons per day, and as to the supply of ore, we have now in sight in this mine a sufficient quantity to last for a long period.

The President's report is as follows: To the stockholders of the California mining company: In presenting my first annual report, I have only to call your attention to the development of this mine which has been going on for the past year almost uninterruptedly. The various drifts, cross-cuts and winzes necessary to future operations, have been opened in a systematic manner and with a view to ore extraction when the proper time comes for that work. The sinking of this extensive joint shaft has been steadily prosecuted until it has reached a depth of 988 feet, and a few months additional labor will find it penetrating

The Heart of the Ore Body

Already known, and furnishing ample facilities for raising ore in quantities sufficient for the payment of handsome dividends.

For the extent of the ore body and details of the work already done, I would respectfully refer you to the report of the superintendent accompanying, and for the receipts and disbursements of the fiscal year just closed to the report of the secretary.

In conclusion I may without hesitation congratulate you in the possession of

The Richest and Most Extensive Mine

Known at the present time, with the prospect of large returns in dividends for many years to come.

THE VIRTUE MINE—The *Bedrock Democrat* says: On last Saturday, Superintendent Hyde shipped bullion to the amount of \$8,139 from the Virtue mine to San Francisco. This was the result of twenty days' run with fifteen stamps. Since our last notice of this mine—some two months since—Superintendent Hyde has shipped \$47,000 in bullion to San Francisco from this mine. This mine, under the careful supervision of Mr. Hyde, is proving to be one of the most regular paying and profitable investments in this portion of Oregon, and will compare favorably with any mine in this portion of the Pacific coast. The mine is in good condition for working, and is being worked in an economical manner. There is a new shaft being started to strike the vein of ore in a new and more favorable place to take out rock than is accessible now. There are several more ledges near the Virtue mine which are proving themselves to be good. In the spring it is the intention of several practical miners to thoroughly prospect the country adjacent to the Virtue mine, and it is thought by those best acquainted with the configuration of the country, that the prospect for the finding of other good mines in this locality are as good as in any portion of the Pacific coast.

BANKS—The Senate has passed an important bill requiring every corporation doing a banking business in this State to keep in its office, in a place accessible to the public generally, and for the public use, a book containing a list of all stockholders in the corporation, and the number of shares of stock held by each; and that every such corporation must keep posted in its office for public use a notice signed by a majority of the directors showing the names of such directors and the number and value of the shares of stock held by each one of them. The law is made to apply to all existing banking corporations as well as those to be formed hereafter.

ORD DISTRICT—The *San Bernardino Times* says: Several gentlemen have recently arrived in San Bernardino en route for Ord mining district, where they have made purchase of some mines. They propose to prospect the mines of that district more fully, and if the indications will warrant them in so doing a stamp mill will be erected at once. Many who are acquainted with that district have great confidence in its mineral wealth, and believe that it will soon be developed. The ore is sufficiently rich to justify working, but wood and water are not accessible, and the rock will have to be hauled quite a distance.

ONE of the most promising new mining districts is located at Belleville, Esmeralda county, embracing several mines, the most productive of which is the Northern Belle, which yielded \$351,000 in eleven months of last year, and disbursed \$350,000 in dividends.

THE Staton quicksilver mine, adjoining the Consolidated Wonder, in the town of Hollister, has been sold for \$250,000.

Ancient Shoes.

Recent discoveries have shown that the modern form of shoe is the same which was in use in Upper Egypt ages and ages ago. The pictures found in tombs in Upper Egypt represent people wearing shoes exactly like ours. It is, nevertheless, certain that the form of these shoes were unknown generally in the East, for chroniclers mention that everybody in the East, in Sparta and at Athens, went barefooted. Sandals came very slowly into use, for they were extremely inconvenient, and Athenians commonly preferred to go barefooted. In Rome, too, even senators long went barefooted. Cato, of Utica, never walked otherwise than barefooted. Shoes were so rare in France in the ninth century, that they were among the presents sovereigns made to each other; for example, Solomon III, sovereign of Brittany, charged the ambassador he sent to Rome to present the Pope in his name a golden statue, a mule, saddled and bridled, thirty ebrials, thirty pieces of cloth, thirty deer skins and thirty pairs of shoes for his servants. The caprices of fashion soon began to mold the form of shoes, and the strangest forms were adopted. Mediaeval chronicles are full of invectives against the shoes *à la poulaine*, which were in great vogue in the twelfth century. The toe of these shoes was pointed upward like the prow (*poulaine*) of a galley; the heel was armed with a spur. A royal ordinance of 1367 interdicted these shoes in France. They nevertheless were still worn by some persons at the court of Francis I. Shoes with excessively broad toes drove these shoes out of fashion. In 1422 hoots made their first appearance. Moxeray mentions that Charles VII was so poor on his accession to the throne that no shoemaker would sell him a pair of hoots on credit. The forms of hoots and shoes have changed repeatedly and annually changed.

Artesian Fire at Lakeside.

Mr. C. W. Clark informs us that he has "struck it" in his well down on the lake. At the depth of 140 feet there rose from his well a volume of gas which ignited upon the touch of a lighted match, and burned with great fury for an hour or two, until partially shut off by the flow of sand, when it was extinguished by closing up the pipe. Subsequently one of Mr. Clark's sons, noticing the continual flow of gas, which showed itself at the orifice of the pipe in little spangles, like beated air, dropped a match into it and looked down to see the effect. He not only "saw it," but felt it and smelt it, too. A shoot of flame, accompanied by a roaring sound, resulting from the expanded gas, threw him several feet from the well, burning his face, whiskers, and eyebrows, and (perhaps,) frightened him some. The well pipes was soon at red heat, the water in the well boiling furiously, the gas struggling through it and twenty feet of sand at the bottom. More pipe has been ordered and a further investigation of the earth's bowels will be made. Mr. Clark has a good thing on his well, if the gas continues flowing steadily in the same volume, as it can be lead into his house for heating purposes, and it is quite possible that it might be utilized for both light and power. Mr. Clark has now got a salt mine and a gas generator on his place, but is going for more. The Lakeside country may amount to something besides a stock range, if those sandlappers don't let it alone.—*Visalia Delta*.

Butte City Mines.

A correspondent at Butte City (Montana) writes to the *Helena Independent* as follows: This lively camp, which your paper and the Territorial press generally have noted, is not a new one by any means. The best inhabitants speak of this as the third waking up, and draw favorable omen from that circumstance.

Professor Hodge, who accomplished so much for Unionville, in your county, in establishing the National works, first visited and resided at a place called Roosevelt, near Butte, bought ledges and set a large number of men at work developing them. His report, a copy of which is in my possession, of the camp, is very full and fully sustains the most of what is called an extravagant one at the present day.

Though a great number of the lodes have changed their names by relocation, yet they prove the Professor's words true. It may be asked if so impressed why did he desert it and Montana? After spending a large sum of money in their development, he located a site for his works, but before he could make a record of it another party had anticipated him and secured the property. The Professor became disgusted, discharged his men and left Butte to sleep. But the camp is now alive.

In my recent visit there I found at least 500 men. Buildings are going up in every direction. Six stores, five saloons, one brewery, two shoemaker and two butcher shops, three blacksmith and four carpenter shops, and two quartz mills of ten stamps each, constitute the business portion of the camp.

THE Union and San Felipe mining companies, of Cerro Gordo, have settled their difficulty and have incorporated with a capital of \$10,000,000. G. M. Fisher, of Oakland, the prominent contestant against Belshaw, becomes one of the directors. The result will be a vast increase in the bullion production.

Rapid Bridge Building.

Our readers have already been informed of this wonderfully short time occupied by Thoe. A. Scott, president of the Pennsylvania railroad, in rebuilding the bridge over the Schuylkill, at Philadelphia, which was recently destroyed by fire. The bridge formed a portion of one of the main thoroughfares leading into that city, and every day's delay of its completion was a serious loss to its business interests. The time ordinarily occupied for the construction of such works would have menaced the success of the work upon the Centennial building, and even the great exhibition itself. Hence the urgent necessity for extraordinary celerity in its reconstruction. In this, both the city and nation's dilemma, Col. Scott stepped in, and rendered the city and country a service which will stand as a monument to his skill and efficiency, perhaps until another centennial anniversary shall roll round.

Years had been required to build the old bridge, and now the necessity required, if within the bounds of possibility, that only a few days should be allowed for its reconstruction. So great was the emergency that the contract was signed before the embers of the old structure had scarcely ceased to burn. How he executed his trust was a mystery until the *Iron Age*, of New York, rose and explained as follows: "Mr. Thomas A. Scott, president of the Pennsylvania railroad, dropped in at the mayor's office and said: 'See here, I'll build you a strong bridge, with double the capacity of the old one. It shall cost \$65,000, \$10,000 less than the insurance on the burned bridge; I'll sell it to the city for cost price exactly; I'll return every cent less than \$55,000 that it costs, and I'll guarantee to have it done by the first of January.'

"When the city authorities had recovered breath this bold proposition was accepted. Mr. Scott had anticipated their acceptance by telegraphing all over the lumber country of Pennsylvania as soon as he made his proposition, ordering the bridge timber to be immediately cut and loaded upon cars to await orders. The instant the contract was signed he sent dispatches ordering that these cars be attached to lightning express trains and whirled toward Philadelphia. Before Mr. Scott's proposition had been officially received everything was ready. About 150 men stood with saws, hammers and spikes in their hands on the banks of the river at the site of the old bridge, waiting for the ordinance to pass, ready to strike the first blow the moment the signal was given.

"It was toward evening on the 5th of December when the contract was signed, and work was begun without an instant's delay and kept up all that night. By daylight and by torches and calcium lights, Sundays and week days, in fair weather and storm, without an hour's intermission, the bridge building was carried on under the direction of Mr. William J. Lockhard, division superintendent of the railroad. Three hours less than twenty-one days from the time the mayor signed the ordinance, or seven days ahead of time, the bridge was finished and formally opened to travel. The men who had been engaged upon it were then treated to a Christmas dinner at the railroad depot in West Philadelphia, and will be permitted to take a well earned rest during the holidays. The bridge is a Howe truss, well constructed of white pine, with flooring of oak. The structure is 540 feet long, the two end spans being each 162 feet and the center span 216 feet in length. The truss is twenty-five feet high in the clear and twenty-eight feet from out to out. The width of the bridge is forty-eight feet, including the sidewalk, which is ten feet wide."

A SINGULAR accident occurred at the Vivian mine, near Silver City, recently, by which two men were quite severely injured. A bucket of water which had been frozen over was placed on the forge to be thawed out, and while one of the men was in the act of lifting it off with a pair of tongs it exploded with great violence, the bucket flying into innumerable pieces, and injuring Samuel Tangie, the blacksmith at the mine, and George F. Oxtan, a miner, very severely. A piece of the bucket, which was made of sheet iron, struck Tangie on the shin, making a ragged wound about an inch in length and tearing the periosteum off the bone. The chances are good for him to lose his leg. Oxtan's principal injury is on his leg below the knee. Both men have several minor ones, which under other circumstances would be considered pretty bad. No cause for the accident, except that some miner had thawed out a giant or herculean powder cartridge in the water during the night, can be given.

A "TRACK FLANGING CAR" has just been turned out of the Central Pacific railroad shops at Sacramento, the object of which is to clear from the track the snow, which frequently packs so tightly beside the rails as to throw off a train. This contrivance consists of a "flat" provided with an axle, upon which are two little steel ploughs, kept down by a spring when in service and thrown out of place when an immovable obstacle is met, only to resume its place when the obstruction has been passed. This car run ahead of a locomotive is expected to do the work of 50 or 100 men.

A FACTORY for making a newly invented explosive material, compared to which giant powder is supposed to be a weakling, is soon to be started at Nevada City.

Useful Information.

Rising in the World.

Experience continually contradicts the notion that a poor young man cannot rise. If we look over the list of rich men we find that nearly all of them began life with little or nothing. To any person familiar with the millionaires of the United States a score of examples will occur. On the other hand the sons of rich men, who began life with the capital which so many poor young men covet, frequently die beggars. It would probably not be going too far to say that a large majority of such moneyed individuals either fail outright or gradually eat up the capital with which they commenced their career.

And the reason is plain. Brought up in expensive habits, they spend entirely too much. Educated with high notions of personal importance, they will not, as they phrase it, stoop to hard work. It is astonishing, therefore, that they are passed in the race of life by others with less capital originally, but more energy, thrift, and industry? For these virtues, after all, are worth more than money. They make money, in fact. Nay, after it is made, they enable the possessor to keep it, which most rich men pronounce to be more difficult than the making. The young man who begins life with a resolution always to lay by part of his income is sure, even without extraordinary ability, gradually to acquire a sufficiency, especially as habits of economy, which the resolution renders necessary, will make that a competence for him which would be quite insufficient for an extravagant person. It is really what we save, more than what we make, which leads us to fortune. He who enlarges his expenses as fast as his earnings increase must always be poor, no matter what his abilities. And content may be had on comparatively little. It is not in luxurious living that men find real happiness.—*Scientific American*.

SHARPENING EDGE TOOLS.—The grindstone should not be less than two feet or eighteen inches in diameter. It should revolve to meet the tool (except when grinding very fine or delicate tools). In grinding a chisel for instance, it should be held firmly on the stone without moving, until a slight wire edge is felt on the other side, which may easily be told by passing the thumb over the opposite side to that which is being ground. When this is felt, turn the chisel over and proceed in the same manner until the wire edge is transferred to the opposite side. It should now be whetted on an oilstone, taking care not to hold the tool too upright, or it will do more harm than good. It should be whetted first on one side, then on the other until the wire edge appears off; now take a piece of deal, free from grit, and draw the edge of the tool across the grain; if it has been properly whetted the wire edge will now be properly removed. Goggles are only ground on their convex surfaces. They should be ground until a wire edge can be felt by passing the finger along the inside of the gouge. This can be removed with the oilstone and deal. While grinding goggles they should be constantly turned from right to left, or the edge will be full of notches. Tools for soft wood should have a long bevel edge to make them cut keen. About a half-inch bevel is best.—*Am. Cabinet Maker*.

A "DOZEN" IN THE POTTERY TRADE.—As the derivation from the French *douzaine* implies, it is generally presumed that a dozen implies twelve things, but in the Staffordshire potteries and in the earthenware trade (queensware in Philadelphia, crockery in other places) a dozen to this day represents that number of any special article which can be offered at a fixed price. That is, the price is fixed and the number to the dozen varies. For instance, the pitchers, which are called "jugs" in the trade, are sold as 2, 3, 4, 6, 9, 12, 18, 24, 30, 36 pieces to each dozen, the price for a dozen being constant. The ordinary pitcher, holding a quart, is a twelve, or twelve to the dozen, while a pint pitcher is twenty-four to the dozen, and is so called when dealing in that size. Few of the articles of the trade are sold in dozens of twelve, plates being almost the only ones, and some of them are sold at sixty to the dozen. Besides these curiosities in figures, the potters have peculiar names—muffins, twiflers, etc.—that make up a trade language of themselves. The quantities for dozens are, we think, yet preserved in the wholesale, or package trade.

A NEW PAPER PROCESS.—It is said that, by a new process recently patented by Eastern parties, it is proposed to manufacture wrapping papers out of green grass or hay. The inventor claims that if grass is used, he can make good paper without cooking the material, and the natural color of such paper will be dark brown—suitable for hardware trade, etc. By this process he claims a saving of five dollars per ton, in fuel alone. If hay is used, it will have to be cooked, and we infer the cost will be about the same as for straw paper.

SOMETHING NEW IN PIANO CONSTRUCTION.—A German tailor at Des Moines has invented a curious sort of piano, the hammer of which strikes bells instead of strings. There are in this piano sixty-six bells, varying from two inches to thirteen inches in diameter, all so adjusted that each bell shall give its perfect tone in response to the touch of the performer's hand on the key-board.

CONDENSED BEER—HOW MADE.—Mr. Lockwood describes, in the *Journal of the Society of Arts*, his patent aloid or condensed beer. Beer is taken at its best condition; its alcohol is separated and saved by a method of gentle distillation in *vacuo*, and the residue is condensed in a vacuum pan, like milk; when finished, it is enclosed in hermetically sealed packages, the alcohol first being added to it again, and acting as a preservative. The fermentation, which was present in the beer when it was taken, is suspended by the heating, and the condensed beer remains sound in this condition, apparently for any length of time, as some exists that has now been kept for nearly two years. When re-made by adding water, it is not wort, but real beer, having all its flavor and alcoholic strength, and lacking only effervescence, which can be quickly imparted by reviving the suspended fermentation for a short time in order to develop sufficient carbonic acid gas to give it the required briskness; or it is fit to drink immediately, if charged with carbonic acid gas, like watered beer.

UTILIZING CINDER PILES.—Quite a business has sprung up at various points in the country in the working of the cinder piles of blast furnaces. For several years iron made in a cupola from cinder piles has been in use in Pittsburgh, and we believe other localities, and is known as Buckeye iron. It is very close, but gives good results in the puddling furnace, especially in mixtures with red short iron. Iron is being made on this plan at Cleveland, at Indianapolis, at Chicago and Cincinnati, and we understand in various other places. There is a vast amount of such waste in all our iron smelting districts; many thousands of tons have been used to fill up bogs and hollows, and to make roads, but the amount yet within easy reach is still immense.

CALMING THE WAVES.—The belief of sailors that rain calms the sea can be confirmed to some extent by pouring water from a watering-pot into a glass jar filled with water, upon which rests a layer of water colored by some substance. This superficial layer will be seen to send rings downward; each ring being set in motion by a drop of the water falling from the watering-pot, and which occupies its center. As in a storm it is only the superficial layer of water which is in motion, the sea would necessarily be calmed by any cause which forced this surface layer of agitated liquid down into that which is at rest. But may not another cause be the retardation of the wind by passing through a thick bank of raindrops?

GOOD HEALTH.

Responsibility of Housekeepers.

(Written for the Press by LORRAINE.)

Health is a matter universally held of the first importance, for without it people are unfit for most of the duties of life, unable to enjoy its pleasures, and usually experience more or less mental and physical suffering.

It has been decided, not only by the most eminent of the medical profession, but by the majority of enlightened people everywhere, that a man's food, that is, what he eats and how he eats it, has more to do with the state of his health than any one other ordinary condition.

If this be the case, it follows that a rather heavy responsibility rests upon the shoulders of the housekeeper, particularly if she also fulfills the office of cook.

Now, the majority of housekeepers are good, well meaning persons, but what miserable work they often make with the preparation of food. If they study the subject at all, it is to make their dishes present a good appearance, and taste well, giving very little consideration to the wholesomeness or unwholesomeness of the ingredients.

People who seem to exercise a fair amount of common sense with regard to other matters, show themselves miserably deficient on the subject of hygiene, as relating to food and the proper time to take it.

One woman forbids her children eating fruit at breakfast time, because they are delicate; and allows them to have coffee, hot doughnuts, and fried pork.

Another housekeeper in cooking beans parboils them in three waters, carefully pouring away each water to get the "poison" out, and cooks all her fruit in a tin pan, allowing it to remain in the pan two or three days, thereby absorbing a quantity of positive metallic poison from the action of the acid on the lead contained in the tin.

Not one housekeeper in twenty enjoys perfect health, yet none of them will admit being troubled with dyspepsia, or even the slightest indigestion.

Mrs. Smith is afflicted with sick-headache two or three times a week, always after eating roast pork or boiled cabbage; but of course those dishes have nothing to do with it, it is constitutional, or is caused by the cold or by the heat.

Mrs. Brown is subject to colds, dizziness, bad breath, no appetite in the morning, and a multitude of aches and pains; but none of these are attributable to the pastry, black pepper, greasy gravy, hot white bread and biscuit that she indulges in every day. O, no! it is the air, or the location of the house, or her having to do housework, or not being able to ride often.

And so she goes on, until too unwell to eat anything at all for a day or two, not even a mouthful of pork and beans, or a bite of mince pie; then she takes a dose of some patent medicine, or puts a plaster on her back, and meditates on the mysteries of Providence.

Providence has little to do with the poor health of American women, the blame rests mostly with themselves.

The health of the whole family is to a great extent in the hands of the mistress of the house. She usually buys the food, and if she does not buy it, she prepares it for the table, or oversees its preparation, and can easily spoil the biscuit or the pan-cakes, or corn bread with over doses of soda, and fill the vegetables and meat with black pepper and pork fat, making them fit for nobody to eat, not even a savage. The other inmates of the house are obliged to eat what is put on the table, or take the alternative of starving, and the result is the general prevalence of dyspepsia.

Heads of families, and particularly housekeepers, should be better informed with regard to the properties of different kinds of food, and the best modes of preparing them, and when that time comes we shall see an improvement in the general health of the people.

Santa Cruz, January, 1876.

Hydrophobia After Three Years.

The Lancaster (Penn.) *Examiner* has an account of the death of Samuel Hance, a black smith, twenty-three years old, in Chester county, that State, after three days' suffering. It says: "He was bitten by a dog in Delaware three years ago while working at smithing. On Thursday Mr. Hance complained of feeling unwell and during the night was taken with convulsions, the fear of water being very marked, the first symptoms of the affection being the difficulty in swallowing water. From Thursday until the time of his death he was frequently seized with the most violent convulsions, which morphine and chloroform were perfectly powerless to check, the slightest disturbing influence throwing him into a spasm—as fanning, a current of air, or a fly lighting upon him. Before going into what proved his last convulsion he requested the attendant to tie him, as he was afraid of hurting some one, being a very powerful man. So the doctor had him tied and held during the convulsion, and he died soon after the convulsion was over. During this convulsion he struggled terribly and snapped his teeth several times, the striking of the teeth being plainly heard. The sufferer was attended by Drs. Horner, Thornton and the Drs. Hoskins, of Chester county. Ever since Mr. Hance was bitten, which was upon the finger, and which was not at all sore during his attack, he had no morbid fear of hydrophobia, being of a rather phlegmatic temperament than a nervous one, and had during the three years been of good health and entirely temperate in his habits. He was married, and leaves a wife and young infant child."

Eyesight of Engine Drivers.

A communication has recently appeared in the English papers addressed by Mr. Watson, surgeon of the Great Northern hospital (Eng.), which is calculated to set railway travelers on the *qui vive* in regard to the possibilities of danger in such traveling from a heretofore unsuspected quarter. This correspondent is actually "convinced" that it is a matter of some uncertainty whether the drivers in charge of trains are not often suffering from an affection of the eyesight. Mr. Watson's far from re-assuring conclusions upon this important subject have been derived from professional attendance upon the late driver of one of the fastest express trains. The condition of this man's power of vision was such as to preclude him from seeing at a distance beyond twenty feet objects which should have been visible at 200 feet.

It is satisfactory to learn that this particular driver, in the face of probable visitations of snow and fog, had the honesty to relinquish work which he could not have performed but with great risk to the public. It is far from clear, however, that every driver afflicted with amaurosis would manifest so laudable an appreciation of the moral code as to resign lucrative employment out of consideration for the public safety. Mr. Watson's communication will doubtless excite many a nervous railway passenger to entertain fresh fears upon the subject of accidents, tho' the possibility of an engine driver being unable to perceive a danger signal 200 feet distant until within six yards of it being anything but a comfortable reflection. The appointment of an oculist for periodical inspections of engine drivers' eyes, in the interest of the public, is a remote but not altogether an impossible contingency.

SEA AIR AND MOUNTAIN AIR.—The difference between the action of sea air and that of mountain air on the human system has been recently explained by Professor Beneke, of Marburg, whose experiments show that bodies part with their heat a great deal more rapidly on the sea shore than among the mountains. Near the ocean the processes of change in the body are accelerated; and sea air is beneficial for persons who are overworked, but whose digestive organs are good. A mountain atmosphere, on the other hand, renders the bodily movements easier by reason of the diminished pressure, and increases the activity of respiration. Professor Beneke thinks that irritable, nervous persons will find themselves better in mountainous districts.

DOMESTIC ECONOMY.

Cooking Potatoes.

"She cannot even cook potatoes," is an expression I have heard more than once. And it is true of altogether too many attempting to keep house. They being such a "stand by" as "something to eat in the house," it certainly is worth while to know how to prepare, cook and serve them the year through.

Growing potatoes should be cooked the same day they are dug; though they will keep a few days if the crevices between them are kept filled with moist earth. The quickest way to get the skin off is to put them in a pail or other deep vessel with bits of brick or stone, and water enough to just cover all, and stirred briskly with a rough stick. The fire must be attended to before the potatoes are put over it. If any fresh fuel is to be added, then is the time, for it is so apt to check the heat and so spoil the potatoes. They must not stop cooking until taken off. They are best steamed, provided the steamer fits half way into the kettle. If the steamer fits just on top, it is hard to get sufficient heat to make them good. They can be put into boiling water and boiled, if the water is all poured off as soon as the potatoes are done, and the kettle put back on the stove with the cover off and allowed to dry. As soon as done, either from boiling or steaming, they should be partially pried open with a fork, so the steam from the inside can escape, then placed in a dish, and hot gravy poured over them. If the vegetable dishes have covers, get one especially for potatoes without a cover, else leave off what you have, for they must not be allowed to steam themselves after they are cooked. If there is no other nice gravy, one can be made of a lump of butter the size of an egg, heated, and a teacup of milk. This will be sufficient gravy for a quart dish of new potatoes; none other should be served with the gravy over them.

After the potatoes are done growing, the skin is tight on them, and they should be washed and steamed, or boiled, like the growing ones, but with the skin uncut. If they are good, and cooked quick, they will burst as soon as done. By the first of January, and all the time thereafter, they are best mashed before serving. If peeled for this before cooking, a very thin peeling only should be taken off, for the best of the potato is just next to the skin, and if boiled after being peeled, this best part is lost in the water. They should be steamed if possible. When done they must be peeled, and mashed quickly, leaving no lumps. As each one is peeled, lay it in a tin pail, or other deep vessel with perpendicular sides for mashing, and break or pry open, but not cut, each one for the escape of steam, while the rest are being peeled. Then if nothing better can be had, and not much better is needed, a fork should be used to beat them against the sides of the pail. Beat briskly until no lumps can be seen. Add salt and rich cream. Turn out in the dish in flakes, leaving the surface to arrange itself; and they are ready for serving. They will be found far more palatable after this treatment than when mashed with a wooden maul, and butter added, then smothered down on the dish, stopping up all the vents for steam to escape. They become waxy after this last treatment, like butter after being worked with the hand in warm weather.

Cold potatoes to be warmed over for breakfast must be sliced thin, and put into hot fat, without a cover over them and salted. They will fry a nice brown in this way, or if not wanted brown, cream can be added and allowed to boil up once.—*Maine Farmer*.

WELSH RABBIT.—In answer to a correspondent we gave a recipe for making Welsh rabbit some few weeks since. Here is another: Olivia writes: "The following recipe for Welsh rabbit I can guarantee as an old English one. It can best be made in a chafing dish, except the indispensable toast, which must be done, of course, before hot coals: Take a good slice of rather new cheese, say one-half pound, cut it into thin chips, do the same with one-eighth of pound of Gruyere cheese. Have your chafing-dish hot, with one-eighth of a pound of fresh butter melted, and stir in the cheese, stirring hard. Add a salt-spoonful of dry mustard, a claret glass full of good ale, or the same quantity of port wine. Pour it hot over the toast."

IMPROVING SPOILED BUTTER.—An excellent process intended to improve spoiled butter was patented in 1859, and therefore expires in about a year hence. It is founded on the fact that the butter in barrels spoils first and mostly from the outside; the hoops and staves are therefore removed from the spoiled butter, it is surrounded with a bag, and the whole buried in charcoal contained in a large barrel or any other suitable receptacle. The well known and wonderful absorbent power of the charcoal for odors removes all strong flavor from the butter, and soon gives it the appearance of a fresh article, saleable in the market at a price far in advance of that which rancid butter brings.

To clean a brown porcelain kettle, boil peeled potatoes in it. The porcelain will be rendered nearly as white as when new.

MINING SCIENTIFIC PRESS

W. B. EWING..... SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, ORO. R. STROGO
W. B. EWING, JNO. L. BOONER

Office, No. 224 Sansome St., S. E. Corner
of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week, 1 month, 3 months, 1 year.			
Per line.....	.25	.90	\$2.00
One-half inch.....	1.00	3.00	7.50
One inch.....	1.50	4.00	12.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collection and renewal. May we not request more of our good patrons to do so?

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Jan. 29, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Fryer Process, 65. Working Gold Ores; A Centennial Exhibition in San Francisco; The Belcher; Coral Reefs and Islands; Notices of Recent Patents, 72. The Raymond & Ely Mine; Haw's Road Scraper, 73. Patents and Inventions, 76.

ILLUSTRATIONS.—Furnace Used in Preliminary Stages of the Fryer Process, 65. Haw's Road Scraper, 73.

MECHANICAL PROGRESS.—Glass Journal Boxes; A New Spark Arrestor; An Iron Carriage Wheel; Case-Hardening Iron; Magnetic Separation of Iron and Steel; Something New in Boiler Flues; The Largest Glass Cylinder in the World; New Mode of Ball Construction; Steel Ships; Softening Castings, 67.

SCIENTIFIC PROGRESS.—The Uses of Ozone; Does Sunshine Put Out a Fire? Scientific Surveys; A New Explosive Compound; Science and the Arts; The New Investigations in Magnetism; Waterproof Tissues and Paper; Interesting Optical Experiment, 67.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 68.

MINING SUMMARY from various counties in California and Nevada, 68-69.

USEFUL INFORMATION.—Rising in the World; Sharpening Edge Tools; A "Dozen" in the Pottery Trade; A New Paper Process; Something New in Piano Construction; Condensed Beer—How Made; Utilizing Cinder Piles; Calming the Waves, 71.

GOOD HEALTH.—Responsibility of Housekeepers; Hydrophobia After Three Years; Eyesight of Engine Drivers; Sea Air and Mountain Air, 71.

DOMESTIC ECONOMY.—Cooking Potatoes; Welsh Rabbit; Improving Spoiled Butter, 71.

MISCELLANEOUS.—Working Quicksilver Ores; The Snake River Mines; Cornucopia District; Repairing; Big Blasts; The Wagonway Mines, 66. The California Mine; The Virtue Mine; Banks; Ord District; Ancient Shoes; Artesian Pits at Lakeside; Butte City Mines; Rapid Bridge Building, 70. The Silver State; Extraordinary Development of Copper in Nevada; Suspension of Coal Mining, 78.

PACIFIC COAST COLLECTION LAWS.—This is the title of a new book by J. H. Jellet, of this city. It is, as the title indicates, a summary of the laws of California, Nevada, Oregon, Washington Territory, Idaho, Montana, Utah, Wyoming, Arizona and British Columbia and of the United States in relation to bankruptcy; also the jurisdiction of U. S. courts, with the names of reliable attorneys in the principal cities and towns throughout the Pacific coast. Mr. Jellet has, for upwards of six years, been in charge of the law and collection department of the mercantile agency of R. G. Dun & Co., and the compiling of this work has suggested itself to him as important to bankers, merchants and manufacturers having business transactions in the Pacific States and Territories, including British Columbia. It has also been prepared with a view to aid attorneys and notaries in matters arising outside of their own State or Territory. A concise statement of the laws relating to the collection of debts is given, in which the compiler has been assisted by various practicing attorneys in the different States and Territories of the coast. The subject matter is divided up in appropriate chapters under the different States and Territories, and a copious index makes the work handy for reference.

THE BRUCKNER FURNACE.—We learn that the Blue Jacket mine has just started two of Bruckner's revolving roasting cylinders, and obtain an average of over 90 per cent. of the assayed value of the ore. Two others are now being erected at Phillipsburg, Montana, and will soon be in operation. The present indication seems to be that the Bruckner roasting cylinder will come into general use. Information concerning these cylinders can be had by addressing Lane & Bodley, Cincinnati, O.

Working Gold Ores.

Great interest is naturally manifested on this coast in anything pertaining to improvements on metallurgical processes, and more especially on those which cheapen the present modes of working. For the past few years very few new processes have been brought before the public, and fewer still have been adopted. But it is not very many years since the whole country was flooded with "new process sharps," each one of whom had a way of working ores which was superior to all others. Naturally many people were taken in with these representations, and the consequence is that now the mining community looks very shyly at anything which savors of change in metallurgical operations.

At the same time they acknowledge that the processes in vogue are not up to what they should be, and look eagerly for some means which will enable them to work their ores up to a better percentage of assay value, and which shall, at the same time, not be too expensive. Of course those conversant with mining affairs on this coast know very well that it is not always the fault of the process in vogue that the ores do not yield as expected. As long as miners are content with from 60 to 85 per cent. of assay value, just so long will millmen return them from 60 to 85 per cent.—and no more. In many instances the tailings are a source of greater profit than the original milling, and no one knows this fact better than the average mill owner. Of late years these circumstances have changed for the better, but still there is great room for improvement.

It has come to be an acknowledged fact, however, that quartz mining in this State has not been generally profitable. There are a number of quartz mines now being worked which yield large revenues to their owners, but where there is one in this condition there are a hundred which do not pay. The consequence of this is that it is difficult to enlist the services of capital to develop gold mining properties. Plenty of money is forthcoming to work silver mines in Nevada and elsewhere, but California gold mines are at a discount.

Many of our gold mines have ledges of sufficient width and amount of sufficient value to be worked at a profit in other countries, but here they lie idle, waiting for a metallurgical millennium, and meantime the gold product of the State falls off from year to year, and the main dependence is placed on the hydraulic mines.

What has been wanted, and what has been really necessary, is some process which would give the miner all the gold in the ore, and not let from twenty-five to fifty per cent. of it go to waste with the tailings. A difference of \$1 or \$2 on a ton will make all the difference between working or not working a mine, and yet sums so small, are considered of little moment in the tailings. The miners have found out by bitter experience that they must be slow, sure and economical to make the quartz mines pay. There must be no leaks of a dollar a ton here, or two dollars a ton there, but every cent must be accounted for. Still, with the utmost care, our present methods of milling and working gold ore have not been satisfactory, a fact we are forced to acknowledge with reluctance. Within the past few months the California quartz miners have begun to hope that the Fryer process would solve the problem, and they are now waiting somewhat impatiently to learn the details of the process. We give in another column a description of the furnace used by Mr. Fryer, and will soon publish a description of the whole matter, so that those interested can judge for themselves. For the present we must all be contented with the assertions of those who have seen the process and its results, viz., "that it is a success."

A Centennial Exhibition in San Francisco.

On Thursday evening last the Board of Managers of the Mechanics' Institute held a meeting to consider the advisability of holding an exhibition this year. The question was fully discussed at the meeting of the managers, the result of the discussion being the adoption of the following:

WHEREAS, A request has been submitted to this Board, signed by a large number of our best citizens, that an industrial exhibition be held under the auspices of the Mechanics' Institute and the management of the Board, during the present year, and with a view to celebrate the one hundredth anniversary of our nation's birth, in view of the reasons therewith presented, and the general desire to have an exhibition in this city,

Resolved, That an industrial exhibition be held in this city on the 8th of August next, with the usual ceremonies.

The Fair, as will be seen by the foregoing, is announced to open August 8th, and while no time has been fixed for closing, it is conceded that it will remain open until the middle of October. An effort will be made to secure a display of the products and a representation of the industries of the States of California, Oregon, Nevada and the Territories of the Pacific coast.

Some time next week a meeting of the Trustees will be held to reorganize as the Board of the Eleventh Industrial Exhibition.

A massive iron suspension bridge will be constructed over the Coyote river, east of San Jose, the coming summer.

The Belcher.

The annual meeting of the Belcher mining company was held on Tuesday last, when the election of officers took place. The mine paid a dividend last month for the first time in a year, but as the prospects of the mine are rapidly improving, it is hoped that the Belcher will soon again take its place among the dividend paying companies. The Belcher has the best records of any mine on the Comstock lode, and consequently any on the coast, although after this month the Consolidated Virginia will have exceeded it in aggregate of dividends. The Belcher has paid out in dividends the magnificent sum of \$15,085,200, equal to \$136 per share. Its total assessments only aggregate \$660,400 or \$6.35 per share, and it has not levied an assessment since April, 1871. Crown Point up to this month has paid out a total of \$11,588,000 in dividends or \$115 per share, with \$673,370 in assessments; and Consolidated Virginia has paid up to this month \$14,040,000 in dividends or \$130 per share, with \$411,200 in assessments. By comparing these figures it will be seen that the Belcher has paid out the greatest aggregate sum and the greatest sum per share in dividends of any mine on the famous Comstock. Although it paid only \$312,000 as a dividend in 1875 it levied no assessments, and work has been vigorously prosecuted all the time.

The receipts for the fiscal year were: From hullion, \$3,383,873.55; cash on hand, January 1st, 1875, \$242,079.15. The principal items of disbursements were: From dividend No. 34, \$312,000; the aggregate expenses were \$2,846,717.65; cash on hand, \$329,759.45, and a time certificate in the Bank of California of \$148,952.61. There were 34,117 tons of ore worked during the year, which yielded at the rate of \$28.43 per ton. The non-arrival of the Superintendent's report in time to be read at the meeting, and the death of the Secretary (H. C. Kibbe) lately, will account for the absence of the President's report and the detailed items of receipts and expenditures. The time certificate mentioned above represents the indebtedness of the Bank of California at the time of its suspension, and like all other large creditors, rather than have the institution go into bankruptcy, it gave it an extension of time to pay its indebtedness. The mine, as will be seen by our Mining Summary, continues to yield well, especially the 1500-foot level, the ore from which runs very high in gold.

Coral Reefs and Islands.

This was the subject of Professor Joseph Le Conte's second lecture (the first of which we published last week) before the School of Mechanic Arts, delivered last Saturday. The growth of coral, he said, which has been continued from the time the bottom of the Pacific began to subside until the present time, goes beyond the present geological epoch. One foot of growth per century, corresponding with one foot of subsidence, for a depth of 10,000 feet, would be just 1,000,000 years. Dead corals at a depth of 250 feet would represent a period of from 12,000 to 15,000 years. Below that depth there is good reason to believe that the coral goes beyond the present geological epoch, and is prolonged throughout the whole tertiary period. Corals continue to live and to build at depths not exceeding from 60 to 100 feet in open sea, and this shows that the same causes which operated to form land in past times are still operating. Limestone, which forms so large a portion of the earth's strata, he believed to be chiefly the product of organic growth; and he was of opinion that the whole western side of the American continent, from the Mississippi westward, has been upheaved higher and higher as the correlative of the downsinking of the Pacific bed. This upheaval has proceeded to the extent of 8,000 feet along the plateau from the Mississippi westward, without taking into consideration the mountain chains, and as the general surface of the country rose higher and higher, those wonderful canons, eroded by such rivers as the Colorado, were formed gradually. The lecturer then entered upon the principal theme of his lecture—the coral formation of the coast of Florida. The southern point of the Florida peninsula he examined with Agassiz in 1850 and 1851. Before that date the whole of Florida was supposed by geologists to belong to the tertiary age, but the investigation demonstrated that Florida is a recent coral formation, belonging to the present geological epoch, or at all events is subsequent to the last, and that the formation is still in progress. The southern part of Florida is composed wholly of limestone, twelve or fifteen feet above sea level. In the interior of the southernmost part are the Everglades—a swampy ground, dotted with hummocks, not more than two feet above the surface of the sea. Outside the coast line of the mainland runs the line of the Florida Keys, 150 miles in length, and terminating in the Tortugas—none of which islands are more than fifteen feet high. The water between the Keys and the mainland is very shallow. In the chain of the Keys are a number of islets called Mangroves, from being dotted with trees of that name. These are formed of mud, and are only a foot or two above the water. Lying outside of the Keys, which are of limestone, is the living barrier of

coral reef, between the great semi-circular sweep of which and the island of Cuba runs the swift current of the Gulf stream. The whole of lower Florida, from the land north of the Everglades, a distance of 300 miles, has been demonstrated to be a coral formation. The Everglade swamps, lying between the limestone on the north and the limestone on the coast, have simply been formed by the mangroves, whose spreading roots, intercepting the sediment, rapidly advance from the sea shore and form land; and the shoal water between the Keys and the coast is the counterpart of the Everglades before the mangroves formed the land. In time the deep channel between the Keys and the outer reef will fill up, and the outer reef will become the southern boundary of Florida. Mr. Le Conte did not think the coral formation will proceed beyond the present outer reef, because the Gulf stream runs too strong to deposit the sediment necessary as a formation for coral building in deep water. Between this reef and Cuba the water is almost unbottomable, and corals do not live at a greater depth than 100 feet.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

ANIMAL EXTERMINATOR.—Valentine Schmidt, S. F. (an interest assigned to H. P. Wakelee). The object of this invention is to so prepare grain which has been saturated or coated with a poisonous compound for the purpose of exterminating ground squirrels and other animals, that it will become a permanent and fixed poison, capable of being transported from place to place, keep a good length of time without becoming spoiled through must, decomposition or otherwise, and always be ready for use. Heretofore when poisoned grain has been used for exterminating squirrels and other animals in the field, it was not saturated or coated with the poisonous compound until it was needed for use, and then when still moist or damp it was distributed in the field. This invention consists in fixing the poisons coating or covering upon the grain in a permanent manner, so that it can be packed in cases, tins or packages, and sold as an article of commerce and always ready for use.

WASHING MACHINE.—Orville V. Roe, Chico, Butte county, Cal. This improvement in washing machines consists in securing inside of a tub two corrugated rollers, one above another, the upper one of which can be rotated by means of a crank, so that the clothes to be washed can be run through between the two rollers and thus cleaned. The exact method of corrugating upper and lower rollers is immaterial, but the inventor prefers to work alternate corrugations and narrow, plain spaces, so that lintons coming under the upper roller cannot catch so as to break, and the upper roller has large grooves so that the buttons can turn either way. This provides a cheap and effective washing machine. The clothes may be either passed through between the rollers, or they may be inserted between them and held, so as to rub any soiled spots.

OPERATING ELEVATOR AND OTHER VALVES.—Philip Hinkle, S. F. This is a novel device, which may be employed to operate elevator and other valves when it is necessary to open one and close another valve at the same time. It consists of a slotted segment formed on different centers, and the stems of the valves are moved by this slot. The outer edge of the segment is provided with teeth, and a pinion mounted upon the axle of an operating rope pulley serves to turn this segment in either direction as the case may require. By this peculiar construction the inventor is able to open the valves with a direct motion and control the supply of water with accuracy.

COMBINED PUMP CONDENSER AND HEATER.—J. A. T. Overend, San Francisco. The object of this invention is to provide an improved means of condensing the exhaust steam from engines, and at the same time heating such additional water as may be needed to condense this steam to a point high enough to allow it to be economically fed to the boiler by means of a novel pump, which is combined in the same device.

BRIDLE BIT.—Hansen H. Soren, San Francisco. This inventor patents an improvement in bridle bits, which consists in constructing the bit in two parts, so that it can be easily separated and removed from the mouth of the animal without detaching any portion of the bridle. This provides a simple means of allowing a horse to be fed without the usual removal of the bridle.

CATTLE WASH.—Albert Sievers, S. F. This is an improved wash or cleaning fluid for cleaning horses, cattle and sheep, and for destroying insects which breed upon cattle and sheep. The wash is made of substances which will not injure wool and its only effect on the skin of the animal is of a curative character.

A BILL has been introduced in the Legislature to regulate the price and quality of gas in San Francisco.

The Raymond & Ely Mine.

The Raymond & Ely mine is the representative mine of Ely district, and just at present the fate of the district seems to hang upon whether ore is found below the "water level" in that mine or not. The mine ceased paying dividends in September, 1873, since which time, although work has been steadily prosecuted, it has not paid. The Raymond & Ely gave Pioche the prominence it at one time held, and has a very good record. It was opened in 1870, and in 1871 yielded in bullion, \$1,361,000, paying from that amount as dividends, \$615,000, which was forty-five per cent. of the yield. In 1872 the bullion yield was increased to \$3,694,000, of which fifty-five per cent., or \$2,070,000 was paid out in dividends. In 1873 the mine produced 2,365,352, but only paid out \$390,000 in dividends. In that year the mine was involved in very expensive litigation, paying out for law expenses, \$289,849, and for purchase of property and claims, \$288,173.

The mine is well supplied with excellent hoisting works, capable of working to a depth of 2,500 feet. It owns several mills at Bullionville and has complete works in the shape of engine house, boiler house, foundry, machine shop, ore house, blacksmith and carpenter shops, etc. The first series of ore deposits was exhausted in 1873, and the work of exploration has failed to develop any new bodies. Work has been continued with the hope of discovering new deposits corresponding in character with the rich ores of former years.

The annual meeting of the company was held this week, and the President in his report says the aspect of the mine presents the adoption of either of the following alternatives:

"From the present aspect of the mine, unless favored in the way of striking other bodies of ore than those now being extracted, we cannot reasonably hope the bullion yield to be enough to meet current expenses.

"To reduce expenditures would be to relax the vigor that has been pursued in the explorations of the larger extent of the virgin ground of the company, which not to do, would in the end prove unwise economy.

"There are but two courses to adopt, either cease doing dead work (or prospecting), or push forward the general system of exploration that has been pursued until it be well established that there are no more profitable mineral deposits in the mine. If the resources of the mine are inadequate to pay current expenses, assessments are the only alternative to meet the deficits between the receipts and disbursements of the company."

This being the representative mine of its district, we make the following extracts from the very full annual report of the superintendent. It says:

During the year just closed there has been extracted from the mine 13,544 476-2000 tons of ore, the greater portion of which was taken from the western portion of the company's ground. Previous to the commencement of the year the eastern portion of the company's ground had been prospected to the water level and proved comparatively barren along the water line; and the new and powerful pumping machinery which was erected in the early part of the year has proved inadequate to the requirements of deep workings. Consequently but little progress has been made in exploring the mine below the water level. Several ineffectual attempts have been made to continue the main shaft downward, but the pumps not having sufficient capacity to remove the water the work was discontinued, and for the past four months the pump has been running up to its full capacity and thus far has failed to remove the water so that sinking could be resumed. [We see by the Pioche Record, however, that since this report was printed the water has been drained to the bottom and prospecting commenced again.—EDS. PRESS.] The most productive portion of that ground has been between the eighth and ninth levels. To the west of winze No. 2 there has been a continuous body of good milling ore, extending 400 feet in length, varying from twelve inches to seven feet in width. This ore shoot terminates about twenty feet to the west of winze No. 4, on the eighth level, at which point a cross-head makes in, dipping to the west on an angle of 45 degrees, which cuts the vein entirely off, not even leaving a trace behind. The west drift on the 8th level was continued on through the cross-head and has penetrated the formation to the west of that point, a distance of 218 feet, and at present the face of this drift shows a mixture of talc and limestone, principally the latter, which is the mountain rock. This drift is still being pushed ahead (it has now a total length of 1,921 feet) in hopes that the quartzite may rise to the west of the formation now being penetrated by this drift.

A prospect drift was run south from the main west drift on the 8th level, at a point 1,132 feet west of the main shaft, and carried ahead a distance of 153 feet, at which point a stratum of ore eight inches in width was disclosed, which was followed to the west a distance of twenty-three feet, at which point a cross-head made in the face of the drift, which cut the vein entirely off.

A winze was started and carried down on the ore streak a distance of 125 feet to the 9th level;

the entire distance sunk showed a continuous streak of ore varying from eight to ten inches in width.

The west drift on the 9th level was continued up to and beyond the same cross head found on the 9th level, where the same formation was encountered as shown on the level above.

The cross-cut was also run south from the west drift on the 9th level, to intersect the south vein, a distance of 154 feet, at which point a connection was made with the winze sunk from 8th level. At the point of connection the eastern limit of the south vein is defined by a cross-head which made in at the bottom of the winze on the 9th level, and to the east of this cross-head no trace of the fissure has as yet been found. To the west of this cross-head the vein is followed westward a distance of 115 feet, at which point another cross head makes in, which cuts the fissure off entirely; still the drift has continued on through the cross-head, and to the west of that point 60 feet, where the quartzite formation becomes very regular and the throw of the vein always being to the south, running westward when displaced by these cross heads. We are at present engaged in running a cross-cut south from the end of this drift, which has now a length of 40 feet, for the purpose of determining whether the south vein continues to the west of this cross-cut or dies out at that point.

Several winzes have been sunk from the 9th to the 10th level, along the line of the ledge. These explorations show the vein to be strong and well defined, but comparatively barren; but the trend of the ore-shoots being to the west, gives reason to hope that ore will be found in paying quantities to the west of this point.

The west drift on the 10th level has been continued ahead until it now shows a length of 1553 feet. The formation being penetrated in hard quartzite, with only a seam to point out the line of the fissure; but as the No. 3 winze, being carried down from the 9th level, is coming down but a short distance ahead of the face

HAW'S ROAD SCRAPER.

of this drift, and is showing a strong, well defined vein, with some promising indications of ore, we may expect to meet with a favorable change in the face of this drift very shortly.

A cross-cut was run south from the west drift on the 10th level, at a point 1,270 feet west of the main shaft, and carried ahead 44 feet, at which point we found a seam or separation in the quartzite, which proved to be the continuation of the south vein downward. A drift was carried to the west on this seam a distance of 73 feet. The entire distance showed the vein to be very small, and, at intervals along the line of the drift, a frosting of ore was found adhering to the walls of the fissure.

A winze was started at a point 1,057 feet west of main shaft on 10th level and carried down a distance of 86 feet, at which point the influx of water was so great that it could not be removed with the appliances we had at our command. Hence, work was discontinued, and at present there is 12 feet of water in the bottom of the winze.

The west drift on the 10th level has now a length of 1,104 feet. The face of drift shows a mixture of talc and quartzite, with occasionally some small spots of very base ore. We were compelled to discontinue work in the face of this drift a few weeks ago, in consequence of not having sufficient air to prosecute the work in connection with the raise which we are at present engaged in running no to connect with the bottom of winze sunk from 10th level. This raise has now a length of 78 feet, which leaves a distance of 28 feet to raise before the connection will be made with the bottom of winze. This connection, when completed, will furnish a good circulation of air, when the work on the 11th level can be prosecuted to advantage.

We are at present engaged in running an up-raise from west drift on eighth level, at a point 1,520 feet west of the main shaft, which has now a length of eighty feet. This raise is furnishing some very fine ore; but, so far, the ore streak is very limited in extent; but as the raise is being carried up two hundred feet west of the Page & Panaca workings, and in a country entirely unexplored, it is reasonable to believe that our efforts in this locality will be rewarded by the development of some paying bodies of ore.

We are also engaged in extending the main drift on the fourth level westward. At the point of commencement the fissure is strong

and well defined, and occasionally shows some promising indications of ore. The only bad feature that presents itself at this point is the hard, smooth foot-wall, which is regarded in this locality as an unfavorable indication of ore; but the ground being very changeable, this unfavorable feature may soon be displaced by more promising indications.

In consequence of the pumps not having sufficient capacity to remove the water the Lighter shaft has only been extended downward 61 feet during the year, making its total depth 1,275 feet. The pump is working very satisfactorily, and is gradually exhausting the water, and I believe we will be able to resume sinking in a few days. [It has been resumed.]

The Burke and Creole mines, belonging to the company, have been allowed to remain idle during the greater portion of the year. After a thorough examination of these mines I decided to apportion them off on the different levels, and let contracts to individual prospectors, allowing them to extract ore from the old abandoned levels of these mines at their own expense and pay the company 40 per cent. of all the ores extracted, and the other 60 per cent. to be worked at the company's mill, if desired; but so far, no revenue has been derived from this source, as the explorations made by these parties on the different levels have proved unprofitable and disclosed but very little ore.

The company's thirty-stamp mill at Bullionville is in good condition, and is being run up to its full capacity. The twenty-stamp mill has been idle the greater portion of the past year, having only run two months on tailings in the early part of the year.

Ores Extracted.

There were 13,714 1-5 tons of ore extracted, and there remains upon the mine and mill dumps 813 4-5 tons. 12,592 3/4 tons milled produced in bullion \$659,471.11, being an average yield of \$52.60 per ton. The ore was worked up to a percentage of 63 8-10. 13,681 tons tailings yielded \$78,793.31, which is at the rate of \$5.76 per ton. The superintendent esti-

mates the value of stores at the mine and mill at \$63,854.83.

The Secretary makes the following report:

Disbursements.

For balances of last fiscal report, since liquidated—superintendent's drafts, \$56,153.51; Union iron works, \$19,902.81; Bank of California, \$49,226.06; total, \$125,282.38. For mine properties—settlement of adverse claims, \$23,094.50; law expenses, \$49,277.55; total, \$72,372.05. For construction and improvements at mine—cost of works at Pioche for current year, \$31,610.24. For mining—extracting ores, \$241,447.65; dead work, \$200,898.77; total, \$502,346.42. For milling—reduction of ores, \$268,674.23. For mine pump construction—cost of works during current year, \$54,826.71. For miscellaneous expenditures—discount on bullion for current year, \$73,229.28; State of Nevada bullion taxes, \$6,293.31; State of Nevada property taxes, \$6,091.16; insurance premium on mill property, \$5,600; telegrams to and from San Francisco, \$420.85; freight on bullion, \$491.20; general office expenses, \$10,483.83; interest, \$8,522.42; total, \$110,432.05. For Nevada Central railroad, \$34,385.50. Total disbursements for the term, \$1,199,930.48. Unliquidated balances—Magnet mining company, \$10,677.05; Hermes mining company, \$144; D. M. Tyrrell, general superintendent, (current balance), \$579.46; bullion in transit, \$58,339.65; cash balance in bank, \$39,775.03; total, \$109,515.19. Grand total, \$1,309,445.67.

Receipts

From balances of last fiscal report, since liquidated—bullion in transit, \$22,196.02; inventory of supplies at mine, \$5,665.25; inventory of supplies at mill, \$58,532.42; total, \$86,393.69. From bullion yield of company's mine—product of ores for current year, as per exhibit No. 2, \$738,305.97; from ore sales, \$5,943.79; from sales of mine supplies, \$1,903.84; from sales of mill supplies, \$1,013.66; from Pioche Phoenix mining company, \$2,500; from machine shop and foundry, \$3,157.47; from assessments, \$330,204.30; total receipts for the term, \$1,169,422.72. Unliquidated balance—superintendent's drafts on San Francisco office, outstanding, \$140,022.05. Grand total, \$1,309,445.67.

The past five years the company has produced \$8,806,286.75 in bullion, and out of this amount disbursed \$5,000,926.28 in dividends. The last one paid was September, 1873.

Haw's Road Scraper.

We illustrate on this page a handy, simple road scraper, invented by R. A. Haw, of Eureka, Humboldt county, California. It is intended principally for work on roads, but may be used for leveling off uneven ground, scraping side hills and work of like character. It has been in use in various parts of Humboldt county for a year or more past, and the inventor has numerous testimonials from road overseers, farmers and others as to its efficiency.

The machine, as will be seen by the engraving, is made of wood, and weighs about 400 pounds. The scraper portion has a width of twelve feet, is set at an incline from the frame work and is shod with steel. The main weight of the machine rests on a pair of castor wheels to which are attached levers to raise or depress the scraper as circumstances require. The portion in the rear of the scraper itself is V-shaped and made of strong timber.

The machine is drawn by two teams. From the lower inside corners of the scraper a curved beam passes up and over the top to the front at each corner, and to these beams the teams are attached. The driver of one team rides on the scraper to operate the levers to suit the varying requirements of the ground. The angle at which the scraper is to be drawn is regulated entirely by the teams. If it is to be drawn at an angle so as to throw the dirt to one side, one team is allowed up so that the other draws the corner ahead a little and then both teams are driven at the same speed. The lower edge of the scraper is curved slightly so as to give a rounded surface to the road.

The machine is perfectly adapted for the purposes for which it is designed. It will fill up depressions and take down elevations or lumps on the road, giving a uniform surface. It is much lighter than ordinary implements of the kind, and requires few horses to do the work. Four horses are needed to work it properly. The machine is so constructed as to work on the edge of a ditch or gulch, and drag the dirt from the edge to the middle of the road, without throwing any of it into the ditch. With it also, work can be done close up to a bank or cliff without the team being in the way. On the edge of a ditch, the teams are in no danger, as they draw the scraper obliquely after them, so that it scrapes even over the edge and draws the dirt into the road.

The raising and depressing levers are arranged by means of notches, so as to keep the scraper in any position required with reference to height. The inventor shows us many testimonials as to the efficiency of the machine, and informs us that all who have used it are perfectly satisfied with its operations and give it high praise. It is essentially a labor-saving machine—doing away with the use of pick and shovel in repairing roads; and, at the same time, doing the work quicker, cheaper and better. Those desiring further information can address the inventor, care of Dewey & Co., 224 Sansome street.

MINING SALES.—The Kansas and Nebraska gravel claims, belonging to Evans & Davis, near French Corral, have been sold to a party of Chinamen for \$14,000. The well known San Bruno mine at Mosquito gulch, Calaveras county, owned by Messrs. Hoerchner, Seigler & Key, has been sold to N. Sackrider, Esq., of San Francisco. Rumor says that \$10,000 was the price paid. The San Bruno has for a number of years been classed among the best paying mines of the county. The *Inyo Independent* says: J. J. Dolan, who six months ago bonded the Minnenta and several other mines in Lookout district, on Tuesday last consummated the purchase and went below, with the four parties from whom he purchased, to see Mr. Lent and others for the purpose of having all the necessary papers drawn and the money, \$30,000, paid over. Mr. Dolan informs us that active operations will be commenced immediately for the development of this splendid property.

MINING PATENTS.—Patents have recently been issued for the following mines: California, Amador county, Christian Harney and others; Gray Eagle, quartz mines, J. G. Adan and others; New London, quartz mine, Martin Nester and others; Volunteer company, quartz mine, El Dorado county, John Summerfield and others; Willow, placer, E. G. Telor; Ohio tunnel company, placer, Bonney, Mooney and others; Gray Eagle, quartz mine, W. K. Grimes; Eureka, quartz mine, Nevada county; N. Bloomfield gravel mining company, placer, Charles F. Bates and others; Local Option, placer, Flacior and Nevada counties, B. H. Bartlett; No. 1 lode, Eureka county, Nevada; K. K. Consolidated mining company (Surplus, Porter and Brown lodes), J. F. Rooney and others; Fourth of July lode, White Pine county, B. F. Brooks and others; Sunbeam and Emerald Isle lodes, Utah.

The boring of artesian wells is going on all over the southern section of Los Angeles county, the artesian belt seeming to range from Downey to the county line, and water occurring at a depth of from sixty to three hundred feet.

There is so much water in the lower levels of the K. K. mine near Eureka that pumping machinery is an absolute necessity, and about \$50,000 will soon be laid out for that purpose.

E. T. MENOMY
Proprietor.At a Stated Term of the Circuit Court
of the United States of America of the Ninth Judi-
cial Circuit in and for the District of California, held
at the court room in the city and county of San Fran-
cisco, on Thursday, the 30th day of September, in the
year of our Lord one thousand eight hundred and sev-
enty-five. Present—The Honorable Lorenzo Sawyer,
Judge.Nicholas Selbert, complainant, vs. Wm. T. Garratt,
defendant—In equity.

DECREE.

This cause came in to be heard at the February
Term, A. D. 1875, of this Court and was argued by
counsel and thereupon upon consideration thereof, it
was ordered, adjudged and decreed, as follows, viz:
That defendant, William T. Garratt, was not the first
or original inventor, or discoverer of the improvement
or discovery claimed by him, in and by those certain
reissued letters patent of the United States, number
five thousand three hundred and twenty-eight (No.
5328), for an alleged new and useful improvement in
lubricators, issued to said defendant, William T. Gar-
ratt, on the 18th day of March, A. D. 1873, and is not
entitled to a patent therefor, and that said reissued
letters patent, number five thousand three hundred
and twenty-eight (No. 5328) are declared void and the
same are hereby vacated and set aside by reason of their
interference with those certain letters patent of the
United States, number one hundred and eleven thou-
sand eight hundred and eighty-one (No. 111,881) for a
new and useful improvement in lubricators, issued to
complainant, Nicholas Selbert, on the fourteenth (14th)
day of February, A. D. 1871.It was also further ordered, adjudged and decreed
that complainant do have and recover of and from de-
fendant his costs and expenses to be taxed herein.
(Signed) LORENZO SAWYER,
Circuit Judge.The above decree has reference to "Selbert's Enreka
Lubricator" for oiling the valves and cylinders of
steam engines.It has a glass gauge and condensing pipe, or reser-
voir, with a regulating feed valve, and works as fol-
lows: As the water of condensation is admitted, under
the oil, just so fast the oil passes out at the top through
a pipe into the steam pipe to oil the valves and
cylinder.Parties who infringe or purchase the infringed
lubricators, will be held strictly responsible.
N. SEIBERT, Patentee,
125 First Street, S. F.

CHAS. H. PHELPS,

ATTORNEY AT LAW,

306 PINE ST., N. W. Cor. Sansome, SAN FRANCISCO

Special attention given to cases involving Min-
ing, Patent or Commercial Law.N. W. SPAULDING,
Saw Smithing and Repairing
ESTABLISHMENT.

Noe. 17 and 19 Fremont Street, near Market.

MANUFACTURER OF

SPAULDINGS'

Patent Tooth Circular Saws.

They have proved to be the most durable and economi-
cal Saws in the World.

Each Saw is Warranted in every respect:

Particular attention paid to construction of

Portable & Stationary Saw Mills.

MILLS FURNISHED AT SHORT NOTICE

At the lowest Market Prices.

DAVID WOERNER,

COOPER,

No. 104 and 112 Suez St., San Francisco.

Wine Casks, Tanks, Tube, Pipes, Beer Bar-
rels, etc., Manufactured at Short Notice
and LOW RATES.LUMBER for CASKS, etc., TANKS, etc. Steamed
and Dried if required. cow-bp.

FRANCIS SMITH & CO.,

MANUFACTURERS OF

Hydraulic Pipe,

AND

ARTESIAN WELL PIPE.

Having the Latest Improved Machinery, we can make
it an object to

Mining & Water Companies

OR

WATER WORKS,

To Contract with us for

SHEET-IRON PIPE.

All Sizes Made and all Work Guaranteed

30 Beale Street,

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience,
collected in Europe and America, well acquainted with
correct management of mines and mills, practised in
projecting and constructing mining and milling ma-
chinery, and especially machinery for mechanical ore
concentration, is open for re-engagement, and would
prefer the task of constructing works for mechanical
concentration of low grade ores on a well developed
mine, or of remodeling ineffective works in the ore
milling line for successful operation. Apply to
Messrs. DEWEY & CO., of this office, for reference.

F. MANSELL & CO.,

SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persons engaged in the following business can have
their Signs Painted at contract prices, for goods or
articles in which they trade, viz:Merchant Tailors, Gents' Furnish'g G'ds,
Bootmakers, Furniture Dealers,
Hatters, Jewelers,
Hotele, Piano Fortes,
Wine Merchants, Etc., Etc.

Metallurgy and Ores.

JOHN TAYLOR & CO.,

IMPORTERS OF AND DEALERS IN
ASSAYERS' MATERIALSChemical Apparatus and Chemicals, Drug-
gists Glassware and Sundries, etc.

512 and 518 Washington street, SAN FRANCISCO

We would call the special attention of Assayers
Chemists, Mining Companies, Milling Companies
Prospectors, etc., to our large and well adapted stock

ASSAYERS' MATERIALS

-AND-

Chemical Apparatus,

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value
per ounce Troy at different degrees of fineness, and val-
uable tables for computation of assays in Grains
Grammes, will be sent free upon application.

7v25-tf

JOHN TAYLOR & CO.

Nevada Metallurgical Works,

21 First street.....San Francisco.

Ores worked by any process.

Ores sampled.

Assaying in all its branches.

Analysis of Ores, Minerals, Waters, etc.
Plans furnished for the most suitable pro-
cess for working Ores.Special attention paid to the Mining and
Metallurgy of Quicksilver.

E. HUNN,

C. A. LUCKHARDT,

Mining Engineers and Metallurgists.

RODGERS, MEYER & CO.,

COMMISSION MERCHANTS,

ADVANCES MADE

PAID TO

CONSIGNMENTS OF GOODS.

Instructions in Assaying,

Chemical Analysis, Determination of Minerals, and
use of the Blow-pipe.

HENRY G. HANKS

Will receive a few pupils at his new laboratory, 617
Montgomery street, up-stairs. TERMS MODERATE

LEOPOLD KUH,

(Formerly of the U. S. Branch Mint, S. F.)

Assayer and Metallurgical
CHEMIST,

No. 611 Commercial Street,

(Opposite the U. S. Branch Mint,

SAN FRANCISCO CAL.

7v21-3m

WATER TANKS of any capacity, made entirely
by machinery. Material the best in use; construction
not excelled. Attention, dispatch, satisfaction. Cos
less than elsewhere.

WELLS, RUSSELL & CO.,

Mechanics' Mills, Cor. Mission & Fremont Streets.

3v28-3m-sa

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
for DIAMOND-POINTED DRILLS, now brought to the
highest state of perfection, are prepared to fill orders
for the IMPROVED PROSPECTING and TUNNELING
DRILLS, with or without power, at short notice, and
at reduced prices. Abundant testimony furnished of
the great economy and successful working of numerous
machines in operation in the quartz and gravel mines
on this coast. Circulars forwarded, and full informa-
tion given upon application.

The Silver State.

The Virginia Enterprise, in reviewing the year's work in Nevada, says: Last year, when we published the annual yield of the mines of Nevada, we predicted that in the coming year the yield would be at about the rate of \$1,000,000 for each one thousand inhabitants of the State, which at the time was reckoned at about forty-two thousand. But for the first time the estimate would have been more than filled. The estimate by experts of \$50,000,000 for 1876 is not too large. The present paying mines of the Comstock are offering better promise than they gave a year ago, and we confidently expect that several on the lead which last year made no showing will very soon commence to yield generous returns. In other parts of the State the prospect is brighter than it was a year ago. This is particularly true of Cornucopia, Eureka and White Pine. Valuable recent discoveries have also been made in Austin. The Northern Belle, near Columbus, is a genuine bonanza, and we trust that before the close of the present year Pioche and Aurora will each resume their old places as large lullion producing districts. Tuscarora ought in the early spring to commence adding half a million per month to the product of this State. We expect also before the year closes that the Fryer process for reducing ores will be extensively introduced into the several districts in Nevada. Humboldt county offers a magnificent field for the introduction of that process. Much of the ore there is too base for ordinary mill work. It does not contain the properties to make it smelting ore, and it is too low grade to ship away. If the process is what it is described to be, it is just what is needed, not only there, but in several other districts of the State. Indeed, if all is true that is said of it, its substitution here for the present means of working would reduce the cost very much and add largely to the proceeds. It is well worth the serious investigation of our mining men. But to return to the matter of Nevada's product and Nevada's resources. No country ever offered such a field for the capitalist who desires to invest in mining property. Outside of the range of incorporated mines there slumbers many a bonanza which needs only a little pluck, a little money and some patient, intelligent labor to bring such returns as would make an ordinary fortune seem in comparison but a pauper's inheritance. A flood of water in the Comstock just before the Belcher and Crown Point bonanza was struck, would have made Virginia and Gold Hill almost like Aurora. After the Eureka Consolidated mines were well opened and the furnaces successfully running, a prudent English company declined to purchase for a sum which now, after more than five years of constant working, the property yields monthly. The Northern Belle lay idle for six or seven years, seeking in vain for a purchaser, at a sum which it yields now every ten days. These are samples, and show what is possible in mining. At the same time a man who is made sick by a loss has better stick to dividend paying stock.

Extraordinary Development of Copper in Nevada.

Wonderful as are the mineral productions of the State of Nevada, every day but confirms the conviction that but little is known of the real extent and value of her mineral deposits. Not only are the more precious metals found in untold millions, but the less valuable metals also exist in quantities which, but for the overwhelming deposits of gold and silver, would be sufficient to attract prospectors and capitalists. First comes the intelligence of vast bodies of coal struck in one section, then cinnabar formations of unbroken extent and untold wealth are encountered, and borax, the real uses of which are just beginning to be known to the world, exists all over the State, and now comes reliable intelligence of copper deposits in the range which divides Alkali valley from Masun's valley in the Walker river section. These deposits lie about forty miles south and east of Virginia, and are of unknown extent and value. The ledge is from five to twenty feet in width, has a north and south trend and is well defined, being a contact vein with a western wall of limestone, while the eastern is quartzite. The ore exists in the form of carbonates and red oxides, and is found to be very rich. A few sulphurets have also been found, but none of these have been reduced. Since these gentlemen have been in possession of the claim, they have taken out and disposed of \$50,000 worth of ore, and have as yet scarcely commenced the development of the mine. The cost of extracting and getting the ore to market is now about one cent per pound. The mine is only twenty miles southeast of the El Dorado coal mine, and when the narrow gauge railroad shall have been completed to that point, the cost of transportation of this copper ore will be greatly reduced.—Virginia Enterprise.

SUSPENSION OF COAL MINING.—A dispatch from New York says that at a meeting of several coal carrying and producing interests on the 20th inst. it was agreed that, in consequence of over production and accumulation of unsold coal upon the market, an entire suspension of all mining of anthracite coal for five weeks, from February 7th to March 11th inclusive, be ordered.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound. SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

Millmen, Attention!

CELEBRATED

AMES PORTABLE ENGINES.

From 3 to 40 horse power, manufactured by the Ames Iron Works, Osewego, N. Y., the largest and most complete in all its appointments of any establishment in the United States, constantly employing about two hundred first-class mechanics in the manufacture of PORTABLE STEAM ENGINES, of which they have made and sold thousands and are now turning out at the rate of nearly four hundred and twenty-five per year, which large production they are now preparing to increase in order to meet the rapidly enlarging demand. They have only obtained and merited this great success by producing an engine really superior in design, workmanship and material, as well as economical in the use of fuel and running expenses. They have recently added to and improved them in several points, leaving nothing that can be asked for or desired to make them what we claim they are and what they are determined to make them, always the BEST PORTABLE STEAM ENGINE IN THE MARKET.

Every piece in these engines is fitted to a standard gauge, so we can always furnish duplicates that will fit or replace any piece or portion required at any future time. They are carefully tested with hydraulic pressure of two hundred pounds, fired up and then run with one hundred and twenty pound steam pressure until known to be perfect and complete in all their parts. The boilers are not only made of better material but are much larger for the price and horse power than those of any other build. We ask and court the closest and most intelligent scrutiny of all the detail and general make-up of these engines. They are all furnished with Smoke Pipe, Governor, Heater, Pump, Steam Gauge, Water Gauge, Whistle, Safety Valve, Gauge Cocks and Oil Cups. Complete in every respect. Send for Illustrated Catalogue and Price List.

AMES ENGINE.

HORIZONTAL HOISTING ENGINE.

We are Agents for Rawson's Improved Hoisting Engines and keep both Upright and Horizontal. They are complete in every detail that makes a first-class Hoisting Engine. They are all fired up and run till we know every part is in perfect working order and will give entire satisfaction to the purchaser. Send for Price Lists.

BAXTER STEAM ENGINES.

We warrant our engines to run up to the full rated power. We warrant them more simple, safe, durable, and economical, than any other engine of equal power. Not one in ten of our Engines are run by Engineers. We send plain directions with them so that persons at all acquainted with machinery can run them. Still it is an advantage to persons getting one to have a practical engineer or mechanic to set up and start it. An hour of instruction will save a week of study.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL, MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick Silver.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price \$2.50 coin, or \$3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams.

1867. This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Mill

man, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 176 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M. D. 1867; cloth bound, 114 pages. Printed and sold by DEWEY & CO. Price, \$1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & Co., Mining and Scientific Press Office, S. F.

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC Journal of the Pacific States.

Miners, Assayers, Millmen, and Metallurgist in the United States should take it. Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

Patent Solicitors.

SAN FRANCISCO, SATURDAY, FEBRUARY, 5, 1876.

VOLUME XXXII
Number 6.

Removal of Prominent Manufacturing Firms.

The engraving on this page is a representation of the handsome building just completed at No. 417 Market street, between First and Fremont. The main floor and basement have been taken by Messrs. Fairbanks & Hutchinson, Parke & Lacy and F. Ogden, the whole making a commodious and convenient sales-rooms as there are in the city.

Messrs. Fairbanks & Hutchinson, the California branch house of Fairbanks' standard scales, have recently removed to this new place of business from No. 537 Market street, and now have more roomy quarters, giving them plenty of space for the exhibition of every variety of their goods. Fairbanks' scales are so well known all over the country, and the world in fact, that it is scarcely necessary to say anything concerning them, although but few people have any idea of the enormous proportions of the trade. The manufacturing establishment is at St. Johnsbury, Vt., the town being chiefly dependent for its prosperity upon these works. The works themselves are very extensive and completely equipped with appropriate machinery. The foundry uses an average of twenty-one tons of pig iron per day, about three-quarters of which is American iron. The foundry department alone employs seventy-three men, the castings being of all sizes from the massive lever of the great railway scale to a little iron weight or a tiny balance. The works are run by a 250 horse-power engine, with four boilers.

The enormous quantities of raw material which are annually consumed in these works are perhaps the best indication of their magnitude. Nearly 7,000 tons of iron a year are melted up in the foundry, 500 tons of fine sand are used, while 4,000 tons of coal are used in feeding the numerous fires, and from 2,000,000 to 3,000,000 feet of lumber are required from which to make the wood parts and packing boxes. The total product of the works is over 1,000 scales per week. In 1873 the scales made amounted to 45,177 separate scales, the pay roll amounting to \$370,266. These figures show effectively the magnificent proportions on which the business is conducted, although the business has greatly increased since then. The factory employs from 500 to 600 men on regular ten hour time all the year round.

The branch house here, Fairbanks & Hutchinson, receive all their goods from the Fairbanks works, and keep on hand all the different kinds of scales which are required. This is a branch house, not an agency, and goods can be bought from Fairbanks & Hutchinson the same as from the factory itself. This branch controls all the Pacific coast trade, China, Japan and the islands of the Pacific. China and Japan now use large quantities of the scales and the trade in that direction is increasing quite rapidly. Fairbanks & Hutchinson have in their new quarters a fine salesroom, plenty of space for storage and all the conveniences for carrying on an extensive business.

Parke & Lacy.

Another firm which occupies this building is that of Parke & Lacy, agents for the Burleigh drills and air compressors, the Putnam machine company's machinists' tools, Haskins engines, Wright's steam pumps, mining machinery, etc. These gentlemen established themselves in business in this city about two years since, starting in on a small scale. Their business has steadily increased, and they have now "branched out" more extensively to keep pace with their trade, having now a fine large store with a heavy stock of goods on hand. They make specialties of everything they handle, and as they only keep first-class articles of the kind dealt in, have succeeded in building quite an extensive trade in their particular line. Both of these gentlemen are practical machinists and thoroughly understand their business.

The building is 134x34, and they use about one-half of two floors, the other half being taken up by the before mentioned firm. On the main floor are samples of the machinery in which they deal. They have on hand some ten carloads of the Burleigh drilling machinery,

and as much more of the Putnam Machine Co.'s tools and Haskins engine. They ship about a carload a week, and have about three times the quantity of machine tools of any one house in town.

The big air compressors for the Burleigh drills are of course kept at the warehouse; but in the basement are kept all the rest of the Burleigh drilling machinery, ready packed for

this connection would be superfluous. There are now sent 150 drills of this manufacture in operation in different parts of the coast. The majority of the machine drills used on the Comstock are of this pattern, and the air compressing machinery is now extensively used for hoisting and various other work in the mines, as well as for running the drills. Messrs. Parke & Lacy have been very active and ener-

getic in introducing this machinery, and it is now more extensively used among us than any other of the same class.

Another specialty of this firm is in Putnam machinists' tools, of which a great variety is made. A number of different sized lathes, planers, drills, etc., are to be seen at the store, and a good supply is kept on hand. These tools have a reputation for strength, elegance of finish and accuracy of workmanship, and they have been extensively introduced. Parke & Lacy also have several sizes and styles of the Haskins portable engine, which are furnished, if desired, with boiler and connections complete. Yacht engines of this pattern with reversing gear, etc., are also on hand. These engines have a reputation for economy and strength, and are neatly gotten up.

Parke & Lacy are also agents for the Heald & Cisco centrifugal pump and Wright's bucket plunger pump. Wright's bucket plunger is a small steam pump which may be used as an engine at the same time if desired. The Heald & Cisco centrifugal is designed for raising not as little but as much water as possible, and is not offered therefore for raising very small quantities of water. It is made so as to be able to pump very muddy water, or will discharge pulp, bark, sand, gravel or any such substances which will go through the feed and discharge pipe. It is specially valuable from its heavy throw of water for the surface condensing engines of steamships. These pumps are built up to 35,000 gallons per minute.

Messrs. Parke & Lacy are now much better situated to carry on their business than ever before, having plenty of room, convenient salesrooms, and a large and handsome stock of their specialties. For a young firm they have been very successful and are now established on a scale commensurate with their business interests.

Tulloch's Ore Feeder.

Mr. F. Ogden has also removed from 310 California street to this building, where he has his agency for the sale of the Tulloch ore feeder. These mining appliances are also well known to the mill men of the coast, having been extensively introduced. The machines are simple in construction, and save labor, shoes and dies; and will put through about two tons to each battery, more than can be fed by hand. One man can attend to two hundred stamps if necessary, for twelve hours, with one of these automatic ore feeders. Mr. Ogden guarantees to put the machine to run smooth on any ore that has consistency enough to be scraped. There are now over 100 of these feeders at work on this coast, and those using them have given abundant testimonials to their efficiency.

Messrs. WOLVERTON & CARVER, who have recently bought and been working the abandoned Rocker lode at Butte, Montana, have succeeded in unearthing an extremely rich deposit, some lumps of ore as large as a walnut having been taken out, the specific gravity of which was more than half gold. In one day, recently, they moved and hoisted to the surface over \$5,000 worth of gold.

THE Humboldt foundry made a successful run on heavy castings, Friday afternoon. The charge was the largest yet melted in the cupola, and among the castings molded was a settler bottom, weighing 3,000 pounds, and measuring over nine feet in diameter, for the Humboldt reduction works.

A MONTEA diamond, weighing 300 carats, has been found at Old De Beer's, Cape Town. An old digger by the name of Phillips recently found a superb stone at Du Toit's Pan which weighed 105 carats. He immediately sold it for £3,550.

THE Idaho City *World* of January 4th reports snow three feet deep in Boise basin, and snow-shoe traveling is in order. At Summit flat the snow was from five to eight feet deep—more than usually falls so early in the season.

THE late misunderstanding between the rival Chinese companies at Enreka, caused by the trouble at Virginia City, has been amicably settled and the danger of an outbreak arrested.

THE Elko *Independent* asserts that the Leopold mine at Cornucopia now has 6,000 tons of ore in sight, which will not mill less than \$200 to the ton.

THE schooner *Star of Freedom* sailed from San Diego Saturday for Ensenada bay with lumber and supplies for the mines near there, and will bring from there a cargo of ore.

THIRTY-SIX miles of railroad iron is piled up at Pueblo, to be used in the extension of the Rio Grande railway.

THE NEW QUARTERS OF FAIRBANKS & HUTCHINSON, PARKE & LACY AND F. OGDEN.

shipment. Duplicate pieces, extra parts, etc., of all this machinery can be procured here, so that those using the machinery can replace easily what is lost or broken. This is a great advantage where the delay of a week or more waiting to repair damages causes so much expense.

The Burleigh drilling machinery is now so well known on this coast, and its merits have been so thoroughly discussed and demonstrated by practical use, that any description of it in

getic in introducing this machinery, and it is now more extensively used among us than any other of the same class.

Another specialty of this firm is in Putnam machinists' tools, of which a great variety is made. A number of different sized lathes, planers, drills, etc., are to be seen at the store, and a good supply is kept on hand. These tools have a reputation for strength, elegance of finish and accuracy of workmanship, and they have been extensively introduced. Parke &

Quicksilver Prospects in San Simeon District.

A correspondent of the San Luis Obispo *Tribune* says: If you will spare me the space in your valuable journal, it may interest your readers to know something of the quicksilver prospects in this region. The Oceanic has engrossed the attention of every one heretofore, to the exclusion of the undeveloped mines, that, with the decline in the price of quicksilver, were allowed to lie idle, but which, with the rise in the market, will come into notice again.

This part of the country seems to be full of quicksilver, and there are dozens of claims, good and indifferent. Of the good prospects, the Centennial, formerly known as the "Beehive," takes the lead. It was located nine months since by H. Phillips and D. W. Morrison, but until three or four weeks ago it was scarcely known except by the locators. They have unbounded faith in their prospect, but do not care to "blow" it. They have prospected it but very little as yet, being men of limited means. There is every indication, however, that the mine will soon fall into the hands of parties who will prospect it thoroughly. They have a solid hill with enormous croppings from one end to the other. Old miners tell me it is worth more than the Oceanic was when it sold for \$47,000.

Next in importance is the Solitary, which, though having a splendid prospect, and thousands of dollars' worth of mineral ready for reduction, has an incubus hanging over it, in the shape of a complicated lawsuit, that discourages speculation.

The Patsey Ann, named after the wife of the enthusiastic discoverer, is next in order, and has \$3,000 worth of cinnabar on the "dump," but as yet they have failed to find a solid deposit.

On the hill, just above the Patsey Ann, is the White ledge, which has four claims on the same lode, consolidated, upon which has been spent thousands of dollars in fruitless prospecting. A talked-of lawsuit threatens to bring the White company to an untimely end.

There are lesser prospects, such as the Lucky Shot, the Mercury (once a famous prospect) and hosts of "wild-cat claims."

Though most of them will probably prove worthless, some of them will soon "strike it," and when quicksilver reaches its former price, we will celebrate the Centennial in the San Simeon mining district, by the opening up of a set of mines that will cause the Old and the New Almaden to sink into comparative obscurity.

Sun Spots and the Grain Market.

A German philosopher, who, with the persistence peculiar to that people, has been watching the sun spots day by day for the past forty years, has discovered that they occur with increased frequency at regular intervals of about eleven years. This discovery has also been supplemented by another no less remarkable, viz.: that the maximum variation of the magnetic needle exhibits the same periodicity, and that the two are exactly coincident. It is also found that magnetic storms have the same cycles.

And now comes Professor Jevons, who reads a paper before the British association, in which he cites some very curious relations between the solar spots and some other terrestrial events. He called attention to the fact that Mr. Carrington had traced a connection between the variation of sun spots and the price of grain; also that Mr. Schuster had pointed out that the seasons of superior vintage in Europe occurred at intervals coincident with the eleven year cycles of sun spots. This fact, he said, was substantiated by a reference to the "History of Agriculture and Prices in England from 1259 to 1400," published some years ago by Professor Rogers.

It is found by reference to that work that the prices of the various kinds of produce in England have risen in the first four years of the cycle, but afterwards fallen; and that the maximum of prices occurs on the tenth, eleventh, first and second years of the assumed eleven year periods. These facts are looked upon as especially worthy of note and calling for further investigation.

It was also pointed out that the commercial panics of the past fifty years show a decidedly similar periodicity—the average length of time between the panics being about 10.5 years—nearly coinciding with the eleven year sun spot periods.

Thus it would appear, according to a contemporary, that if Balfour Stewart is right in holding that the sun spot variations depend on the configuration of the planets, it would seem that these bodies are the remote cause of numerous terrestrial phenomena connected with the industrial operations of man, and that the modern astronomer must return by a new road to the ancient astrologer's belief in the influence of the heavenly bodies upon human affairs.

PELICAN MILL.—This fine establishment has been greatly improved and enlarged. It now has a capacity of 350 tons a month. It is supplied with ten stamps, of 650 pounds each, ninety drops to the minute; eight amalgam barrels, holding 2,000 pounds each; five Bruckner cylinders, treating 3,000 pounds at a charge. The power is furnished by water in the summer and by a forty horse-power engine in winter. B. F. Nepheya, a successful mill man, has general charge of the mill. —*Colorado Miner*.

The Famous Mariposa Mill and Mine.

We have information, and that, too, from a reliable source, that it is the intention of the Mariposa land and mining company, some time the ensuing spring, to put a force of men at work on this claim and start the old mill again. This is good news for the people living in our town, and also the county. Our informant is entirely reliable, and was at one time employed on this mill. He further enlightens us that it was told by members of the company that it is their intention, as soon as they strike paying rock in their big tunnel at Bear valley, to commence operations at various points on the grand estate and go for all that it is worth. This embraces our favorite project of introducing water along the divide by means of a canal, which is the grandest of all the enterprises that has been conceived. The success of the Fresno fluming and lumber company shows the practicability of this, and is stimulating the company to action. With a greater supply of water, and timber more inexhaustible, there is every inducement for the company to undertake the project and put it through at an early day. From the day the first blow is struck on this work, the value of the estate will be increased a thousand-fold, and a prosperous future for the town and county of Mariposa. We have ever had faith that there was a brilliant outcome for it, and now we feel assured of the fact. The gentleman to whom we allude has had much experience in quartz mining, and he says that there has never been a day since the old Mariposa was first opened, that, under the right kind of management, it would not pay largely. He says that the stealing from this mine by employees has never been equaled since the first discovery of gold. The vein is well developed, and has as much to recommend it to favorable consideration as any vein in the State. rejoice, people of Mariposa, the day of jubilee is coming! —*Mariposa Gazette*.

The Comstock.

As much as has been said of the Comstock lode those most intimate with it do not comprehend it, while people abroad have no conception of it. Its daily yield is 2,000 tons. That is, from this ore-channel there is every day extracted ore enough to load ten trains of twenty cars each, and those car loads would average \$700 in value each. This is dug out of a space of ground less than three miles in length and less than 400 feet in width. Indeed, when we confine the estimate to the part of the ledge which at this time is yielding ore, we find that a half-mile in length will cover the whole ground. When we compare the stream of gold and silver to anything ever heard of or read of before in history or romance we discover that everything else ever talked about begins to seem small and mean. Dumas pictured a man who was able through his wealth to almost subvert empires and to make fate his servant. And yet, in the next eighteen months, the Comstock will supply money enough to balance the tremendous account which Dumas placed to the credit of the imprisoned sailor. We see figures piled up in the newspapers which, in dollars, represent the National debt. That debt is so tremendous that though the fortunes of forty millions of people, an empire of three millions of square miles with its cities, townships, mines and fertile soil are all mortgaged for its faithful payment, still the promise of the government (which is the people) to pay is at a discount of fifteen per cent. And yet the Comstock is yielding this year and as it promises to yield for many years to come, it will take but thirty-five years to add to the treasure of the earth as much as that debt today amounts to. —*Enterprise*.

The San Diego Mines.

The San Diego *Union* says: Count Dwarkowski, of Julian City, came in last evening and brings a good report from the mines. There is a good deal of activity, and work is being done on all of the claims. We have an interesting statement showing the number of men actually at work on the different mines on the 13th inst., as ascertained by a personal visit to the ground. It should be understood, too, that several of the more prominent mines have been running short handed for the last three weeks, on account of the fact that the supply of giant powder used in blasting was exhausted about the 25th of December. A supply is expected by the next freight steamer, when the working force will be a third larger than at present. The statement referred to is as follows:

Julian District.

Helvetia mine, 18 men, and 8 additional cutting wood, burning charcoal, and at other work outside the mine; Tom Scott mine, 6; Pride of the West, 3; Good Hope, 2; Van Wert, 2; Owens Extension, 3; O'Connor, 2; Gardner, 3; Butler, 3; Washington, 2; Hayden, 2; San Diego (East), 2; Helvetia Extension, 1; Merry Christmas, 2; Mountain Brow, 2; Big Blue, 2; Canadian, 3; Mabel, 2; Belcher, 3; United States Tunnel, 2.

Banner District.

Ready Relief, 12; Hubbard, 4; Chariot Extension, 3; Ella (North), 5; Ella (South), 3; Florence, 3; Kennedy, 4; Cable, 2; The Dane, 1; Madden, 2; Antelope, 2; Sacramento, 3; Hidden Treasure, 4; Extension Hidden Treasure, 3; Kentuck, 5.

Mesa Grande.

Shenandoah, 3; Oriflamme, 2. In the three mills running on the date specified ten men were employed.

The Franklin Claim.

A correspondent of the Dutch Flat *Forum*, (Placer county) writes to that paper as follows: I have perused from time to time, in each succeeding issue of the *Forum*, well written productions of your numerous correspondents from the surrounding districts on mining. The original aphorism "a fait heart never won fair lady" (neither will a dumb pen echo the achievements of wisdom, nor the rewards of merit) prompts this my first effort. Without further preface I venture forth and pluck garlands to decorate the fair brow of the Franklin claim. A few paces from Main street, Dutch Flat, will suffice to tread the boundary line of the claim. It is owned by an incorporated company, among which are represented prominent millionaires—the proprietor of the Palace hotel carves the "fatted calf." Mr. Teafie represents the company here, commands an interest in and superintends the claim. The original Franklin was first prospected and located in 1854 by the superintendent of the modern Franklin enlarged. At that time it only covered a small area; it since absorbed the boundary claims, viz.: Williamaloo and D. F. W. company on Bear river side, on Dutch Flat side, Little Hope, C. P. R. R. company and St. Nicholas. All those claims are now consolidated, containing an area of forty-five acres. Most of the ground has been superficially stripped. The ambition of the primary operators was gratified like the whale fishers, strip off the blubber and leave the mammoth body intact. But we must not reflect on their energy; for like all other pursuits the hydraulic infant has made rapid strides to maturity. The present indications of the claim are auspicious of satisfactory results in the near future. Work on the tunnel and shaft is prosecuted vigorously night and day.

The Shaft.

From the surface the workmen are sinking perpendicularly through the gravel to junction, with an incline running at an angle of 30 deg. through bedrock connecting with the tunnel. Taking the bottom of the tunnel as the base of a right angle, the altitude of the perpendicular to the surface will measure 150 feet. Consequently 100 feet of gravel and 50 feet of bedrock would have to be penetrated, were it not for the prolongation of the tunnel to a point vertical to an indentation on the surface. The gravel extracted from the shaft prospects richly. When exposed to the atmosphere for any length of time it severs from the component parts very easily. It is constituted of conglomerate rock crystals, argillaceous schist or slate, silicates, and is of a bluish color. While I was investigating the gravel "dumps" at the shaft, I noticed several pieces of petrified wood, some of which retained the original grain; others were in an advanced state of decomposition, and were almost reduced to "peat." The tunnel intersects the hill at a low point, in a ravine emptying into Bear river. Its course is about northeast and southwest. It is at present in a distance of 400 feet, and will, when required, be continued until it taps the subterranean channels farther south. The rock through which it has been driven is extremely hard, and by striking it with a hammer sounds like the horn of a blacksmith's anvil. Notwithstanding, the bore, which is 8x6, is as true as an Armstrong "muzzle." The reader who may possess any knowledge of mining, no matter how limited, will readily assert that a piece of mechanism thus could only be accomplished by wisdom not deducted from theory.

The Boxes

For the flume are to have ten inches grade to every twelve feet; in case of omission it would be well to state that they are not erected on a frail or sandy foundation; on the contrary, they are firmly imbedded in rock. That is one of Mr. Teafie's characteristics, "whatever is worth doing at all is worth doing well." The principal essential of gravel mining is to have a securely adjusted "grade" for the boxes, so that the velocity of the water or "tailings" carried through the flume may not be increased or diminished. Twenty-five boxes and three under-currents are in course of construction to the mouth of the tunnel, and will be immediately paved with "riffles." After the escape of the water and debris from the flume, it will empty into a gorge 800 feet from the river. When the washing commences the view from there will be one of indescribable grandeur. Without unforeseen events arise, the Franklin gold mining company will, by the 1st of February, be accumulating amalgam which in 30 days from hence will be coined into "twenty-ties."

STAR DISTRICT.—W. L. French, superintendent of the American Basin mine in Star district, received a box of ore yesterday which was taken out of the mine a few days ago. Some of the specimens assayed \$1,000 per ton in silver and the whole averages \$700 per ton. Work was resumed on this mine a few weeks ago, and the prospects of developing a good lead are very encouraging. From present indication Star promises to prove what many miners always believed it would, a good mining camp. Since the completion of the Sheba hoisting works, by which the mine has been drained, some valuable deposits of ore have been developed at a greater depth than it was possible to sink before, on account of water. The superintendent, Peter Woolcock, is an experienced miner, and is working the mine systematically. —*Silver State*.

The Defiance Mine.

In a late number of the *Bakersfield Courier* appears a description of the mine in Darwin district, Inyo county, from which we extract the following concerning the representative mine and its furnace: The Defiance, showing the greatest body of ore in the district, and being now partially opened and in operation, may properly claim our first attention. This mine was discovered a little more than a year ago. For some time there was some conflicting claims to it, but these are now adjusted, and it is owned by the Defiance mining company, a regular incorporated company. A small portion of the stock only was placed to obtain capital to open it, erect furnaces and get it in running order. This is now accomplished, and the great bulk of the stock remains in the original hands, Messrs. P. Reddy, of Inyo, Sol. Jewett and Judge Colby, of Bakersfield, being really the *bona fide* owners of the mine. It lies about one mile from Darwin, on the east side of Mount Ophir, which is the name of the highest point of the range. The croppings are plainly discernible half way up, jutting out in bold relief on the brow of the mountain. There appear four distinct leads, one above the other, with masses of country rock, as the walls are called, between them. They are of different widths—from twenty to sixty feet on the surface—and all pitching into the mountain. A tunnel, on a horizontal plane, runs in at the foot of the first lead, cutting it obliquely, passing through it into the country rock, through that and through the next lead. It is still being pushed through to cut the four leads which it is supposed converge at a certain depth and form one grand lead, probably one hundred and fifty feet in width.

These leads pitch downward at an angle of about sixty degrees. On the first one a shaft goes down with the incline of the lead some one hundred and forty feet. Here they are opening breasts and drifts, and the character of the ore is improving—the gray carbonates, rich in silver, taking place of the galena. Everywhere, as one wanders through this great mine, above, around and beneath, he is confronted with one great mass of glistening ore; so vast is the quantity that it appears at first sight that it will be impossible to exhaust it, even at the trifling depth that has already been attained. A good wagon road has been made from the mine to the furnace, a distance of seven-eighths of a mile, whither the ore is conveyed. The furnace has been completed but a short time, but everything is found to work perfectly well. It has a reducing capacity of thirty tons per day, and is now turning out about one hundred and fifty bars of bullion per day, worth from \$150 to \$200 each. In the furnace about twenty-five men are employed, in three shifts working night and day. In the mine from forty to fifty men are employed. We cannot close this brief and imperfect notice of this great mine without referring to its superintendent, Mr. P. Reddy, to whose energy, good management and sound judgment the condition of the enterprise is to-day an enduring monument. Here is a great mine, in a fair progress of development, furnace on the ground, and a few days ago twelve hundred bars of bullion on the ground, where but a few months ago there was nothing but a pile of rusty rocks. It cost \$30,000 up to the time the first bar of bullion was turned out. The first month of its operation it will pay its way and the considerable expense incurred in opening it properly. Next month Mr. Reddy expects that the Defiance will declare its maiden dividend. It is certainly no flattery, but simply a just and honest tribute to the superintendent, to say that there is no record in the State of a similar instance in mining.

The Golden Cities.

At a point on the railroad about half-way between Dutch Flat and Gold Run, can be seen the towns of Iowa Hill, Gold Run Dutch Flat and Little York, four of the busiest mining towns, or, taken as a whole, the busiest and liveliest camp in California. In this small scope of territory of about twelve miles in length by two in width, more men are employed and more money paid for labor than in the whole of any one agricultural county in the State. A very low estimate of the money expended for labor alone would place it at \$60,000 a month, which is not by any means the bulk of the expense of mining in this district; but will reach, perhaps, a little over one-third; and the products justify this large expenditure of money. Every claim that is now being worked pays expenses, while there are not a few which are paying handsome dividends to the stockholders, and that, too, with flattering prospects for still larger returns. A glance from the point indicated, and the eye will glance over more gold not yet gathered in than we read of in fabled history, and to which those golden images of the days of Solomon, or all his repented wealth, would be but as a haudful compared with the wealth of the Bank of California. —*Dutch Flat Forum*.

Work is again progressing on the old Union mine at Copperopolis; the mine is being pumped out and there is a prospect for another lively time in that vicinity. The concern is now clear of litigation, and is owned by Messrs. Glidden and Williams, of Boston.

The Humboldt sulphur mines are turning out a product beyond the highest expectations of the owners, and thousands of tons are now in sight.

SCIENTIFIC PROGRESS.

Science and Discovery.

What science and the mechanic arts have done for the world's advancement in comfort may be faintly guessed from the survey of a week's work at the manufacturing city of Birmingham alone. Its results are the making, among other things, of 14,000,000 pens, 6,000 bedsteads, 7,000 guns, 300,000,000 cut nails, 100,000,000 buttons, 1,000 saddles, 5,000,000 copper or bronze coins, 20,000 pairs of spectacles, six tons of paper mache wares, more than £30,000 worth of jewelry, 4,000 miles of iron and steel wire, ten tons of pins, five tons of hair pins and hooks and eyes, 130,000 gross of wood screws, 500 tons of nuts and screw bolts and spikes, fifty tons of wrought iron hinges, 350 miles' length of wax for matches, forty tons of refined metal, forty tons of German silver, 100 dozen of fenders, 3,500 bellows, and 800 tons of brass and copper wares.

By a simple method, now much used abroad, the inner diameter of tires which have been unduly enlarged by the hammer or rolls is reduced with ease. The tire is heated to redness and then plunged horizontally, but only to half its breadth, in water, where it is left until quite cold. This operation is repeated in the same position, and afterward the tire is turned over, and the heatings and plungings applied to the other half. The first cooling produces a contraction of which the part not immersed partakes and thus undergoes a molecular retraction, resulting in a reduction of the diameter. The same effect is produced in the other half during the second operation. In this way, it is said, a tire has been reduced seven units in 85; and four immersions will double the shrinkage. By the method here indicated a ring of Bessemer steel, which had been greatly enlarged under the hammer, was given the desired diameter by heating and immersing thirteen successive times—first the side which was contracted and afterward that which had become enlarged. The correction amounted to nearly four inches.

A mammoth telescope, said to be the largest ever made, is now in process of construction at a factory near Dublin, Ireland. It is building at the order of the Austro-Hungarian government for the new observatory at Vienna, to be finished by the autumn of 1878. The object glasses will have an aperture of about twenty-seven inches. The focal length is to be about thirty-two feet. The great base casting, weighing some seven to eight tons, will form a chamber about twelve feet long, four feet six inches wide, and eight feet wide for the clock, which will be supplied with anti-friction apparatus. The tube will be entirely of steel, and all the various motions of the instrument, as well as the reading of the different circles, will be available to the observer from the eye-end of the telescope.—*Ex.*

The Technology of Iron.

The following interesting items in relation to the technology of iron are from the report of David Forbes, F. R. S., to the Iron and Steel Institute, and published in the *Journal* of the institute:

Magnetism of Iron.

It has generally been accepted that iron at a red heat was incapable of being rendered magnetic, and this was sustained by Eliss, in *Poggendorff's Annals* for 1872; the reverse of this is now, however, maintained by M. Gangain, in a communication to the Academy of Sciences, in Paris, February 1st, who states that if it is wished to saturate a bar of iron with magnetism, the best method of doing so is to magnetize it whilst its temperature is very elevated.

Magnetism of Steel.

Commandant Treve has communicated to the Académie des Sciences the results of experiments made by himself and M. Durassier, the head of the chemical department at the Creusot works, on the connection which exists between the nature of the steel and its magnetic force. Fifteen bars of steel were selected, which were divided into five sets, each of which received a different temper, after which M. Treve magnetized them to saturation, and then determined their magnetic force by the method of deviation. Those bars which contained 0.950 per cent. of carbon, and which were hardened in cold water, gave a maximum of deviation represented by the number 47; whilst a bar with the same amount of carbon, but hardened in boiling water, gave the number 44; and a third bar, also with the same amount of carbon, but hardened in oil of a temperature of ten degs. centigrade (fifty degs. Fahrenheit,) only gave 43, showing that the fluid used in hardening exerts an influence.

The effect of the amount of carbon contained in the steel is also established, for whilst the maximum of deviation of the above mentioned bars, which contained 0.950 per cent. of carbon, was found to be 47, other bars containing 0.250 per cent. of carbon only showed a deviation of 13. In laying down the curves of variation, the influence of the amount of the carbon and of the hardening media was sensible enough, but the effect of the latter was smaller in proportion as the former increased, and M. Treve has ascertained the fact that the magnetic curve of a steel bar coincides with its curve of elasticity, thus proving that carbon not only gives to steel its elasticity, but also its magnetic capacity.

The Relation of Battles to Storms.

It has been observed for many centuries that storms, or meteorological changes of a striking nature, occur during or at the close of great battles. Whether these results are to be regarded as coincidences, or as the sequence of physical disturbances in the atmosphere, is a question not decisively settled. Of the fact that storms do occur in close connection with battles there is no doubt. During the late war in this country, hardly an action of any magnitude took place which was not accompanied with wind and rain. The operations on the Peninsula under McClellan were apparently productive of continuous rains, and in the great fights around Richmond and Petersburg meteorological disturbances occurred which at times seriously impeded military operations. So, too, abroad. The loss of the great battle of Solferino was attributed by the Austrian commander to a terrific thunder storm which burst over the field and obscured movements of powerful masses of the enemy. The decisive battle of Sadowa, which closed the Austro-Prussian war in 1866, was in like manner accompanied by a violent storm. Napoleon was heard to remark that so certain was he of causing rain by the explosions of his artillery during battles, that he disposed his troops in a way to take advantage of clouds when they formed.

No reasonable objection can be urged against the theory that great explosions, producing violent concussions in the air, may change its hygrometric conditions and cause condensation of moisture. Besides the disruptive effects produced in a great battle, there is the evolution of much heat, from the combustion of gunpowder and from the massing together of large bodies of men. Altogether, it is not difficult to find satisfactory causes for sudden meteorological changes during great battles, and therefore wind and rain are not to be regarded as simply coincident with active proceedings in war. It may be urged that our national anniversary, the Fourth of July, is usually clear, notwithstanding the vast amounts of gunpowder burned in all parts of the country. This does not, however, meet the case; the explosions occur all over the country and are comparatively upon a small scale. There is not usually a decided concentration of noise at any one point. If this occurs, a shower is pretty certain to take place. Last year the day was particularly noisy in Eastern Massachusetts, and in the afternoon the most violent thunder storm of the season burst over that section of country. The question is one of much interest to meteorologists, and is worthy of a more careful consideration than it has received.—*Journal of Chemistry.*

Distribution of Temperature on the Earth.

The distribution of temperatures upon the globe is a subject of profound popular and scientific interest. More than any other, it affects the distribution of living forms, not only in zones of climate, but in geological time. The contour of the earth's surface, and the relation of land and water upon it, may produce important local changes, or establish local isotherms and isobars, but these are scarcely more than modifications of grander and more general results. Arctic plants may, indeed, flourish under the equator, but only on mountains where an arctic climate prevails. Heat determines the limits equally of the vine, the palm of the tropics, the cereals of the temperate zone, and the food of the reindeer. Whether or not tree-ferns grow in Pennsylvania, and forests of pine in the Arctic circle, depends on climate. Nor is this a phenomena of the present age only. Geology proves from its records that, while a torrid zone may have existed since climates began, yet polar and temperate regions have witnessed changes both of climate and of life in wonderful succession, and in periods of immense duration.

The causes which have contributed to these results have been sought and studied by some of the most eminent scientists of our time. Humboldt, Sir John Herschel, Sir William Thomson, Lieut. Mury, Sir Charles Lyell, and more recently Dr. Carpenter and others, have investigated the subject in many of its aspects, and their conclusions are before the world; but no one, we believe, has presented it from so many points of view, or attacked its complex problems with greater vigor than Mr. James Croll, whose volume is now before us. His conclusion is, that not only great secular changes of climate, but the distribution of temperatures upon the earth's surface at the present time, are due to causes which alter the volume, intensity, and direction of the trade-winds and other prevailing winds of the globe. For the question at issue is not the amount of heat received upon the earth's surface, but the means by which it is distributed.—*Popular Science Monthly.*

HYDRATED CELLULOSE.—It has long been remarked that, under the influence of acids, cellulose becomes extremely friable. Paper bleached with a too large excess of chloride of lime, and linen submitted to the action of sulphurous acid, which transforms itself into sulphuric acid, may by the least pressure be reduced to powder. M. Girard, after a series of elaborate experiments, concludes that this transformation is due to the fixation of an equivalent of water by the cellulose, and he has produced the hydrate synthetically. It is a white substance, very easily pulverized. M. Girard considers that this hydration of cellulose plays an

important part in the economy of nature, and that the production of rotten wood, ulmine and ulmic acid is always preceded by that of the newly discovered hydrate.

The Danks Furnace in England.

For some reason or other much difficulty has been encountered in introducing the Danks furnace in England. The advantages of this furnace were first brought to the attention of English iron masters at the Dudley meeting of the Iron and Steel Institute in 1871, by a paper read before that body. Although the invention was an American one, Mr. Danks being at the time of the invention an American naturalized citizen, and a resident of Cincinnati, it was at first regarded with much favor in England, for the reason that the inventor was an Englishman by birth—a South Staffordshire man.

At this time it was reported favorably upon and several furnaces were erected and set to work. After a time, however, they seemed to have failed, chiefly from defects in mechanical construction, but in a large degree from the prejudice of workmen against their use on account of their labor saving features. These failures caused much disappointment, and served to prevent their general introduction into other localities.

Experience, however, soon suggested important modifications in their mechanical construction, and time gradually wore away the prejudice which they encountered at first from workmen. This improvement was largely brought about through the efforts of Mr. Robert Heath, of the Ravensdale iron works, of North Staffordshire. He started with six of these furnaces and has since added four more. The practical interest which he took in the matter, and the success with which he was rewarded, induced the Steel Institute, at its last meeting, to visit his works in a body. The visit was very satisfactory, and a report was made to that effect, which will doubtless result in a very general introduction of the Danks rotary puddler in all the great iron districts of England.

Mr. Heath is now rolling Danks blooms into sixteen inch bars, twenty-four feet long. He is also manufacturing heavy plates and a great variety of smaller sizes of merchantable iron, and is perfectly satisfied with the success which is attending his efforts. Iron can be produced by this process very much cheaper than by the ordinary hand work, on which account the success in this direction is considered a matter of much importance to all ship builders, mechanics, engineers and all others who use wrought iron on a large scale. The invention has been considered a success in this country from its very start, perhaps for the reason that various improvements have been introduced from time to time, under the practical eye of the inventor himself, and of course sooner than they could be reached in England.

EXHAUSTION OF THE SOIL BY APPLE TREES.—M. Pierre, a French scientist, calculates that, in a life of sixty years, an apple tree removes from the soil sixty pounds of nitrogen, equal to 11,500 pounds of farmyard dung. To maintain the soil in condition, therefore, about 175 pounds of dung ought to be annually given per tree during the fifty years that it is bearing.

MECHANICAL PROGRESS.

The Screw Propeller—Old and New.

The screw propeller has been in practical use only about forty years, although its ideal origin runs back much farther, and was first constructed for use in the air as a sort of revolving sail. Thomas Jefferson, writing from Paris in 1785, describes a vessel then recently invented, which he examined while in operation. He says the inventor did not know himself the principle of his invention. "It is a screw with a very broad or thin worm, or, rather, it is a thin plate, with its edge applied spirally round an axis. This being turned, operates on the air as a screw does, and may be literally said to screw the vessel along." * * * The screw, I think, would be more effectual if placed below the surface of the water." Mr. Jefferson adds to his notes on this invention that he thinks Mr. Bushnell, of Connecticut, has a prior claim to the invention of the screw as a motive power for vessels. During the Revolutionary war he invented a submarine torpedo vessel, to be driven by screws. This torpedo was the original of Fulton's, and may have been the first instrument of its kind, but the screw had been suggested as a motive power for vessels long before the time of Bushnell. Brande's dictionary says that "the screw propeller is probably as old as the windmill, and a windmill of the construction now usually employed is represented in the 77th proposition of Hero's *Spiritalia*, a work written 130 years before the Christian era." For a century and a half efforts were made to introduce the screw as a propeller of vessels before Ericsson and Smith successfully demonstrated the utility of the screw, and its advantages over paddle wheels. The history of this, as of most other inventions, shows that the world must wait for its laggards; that it cannot advance rapidly along one line of discovery, or of useful application, until it has advanced or is ready to advance along others. Abnormal or premature growths are sure to be "nipped in the bud."

Who Invented the Barrel?

Few inventions have had a wider or more varied usefulness than the barrel; few give such promise of perpetuity. Unique in principle, simple yet singularly perfect in plan and structure, the barrel is little less than a stroke of genius. Who set up the first one? Who first conceived the happy thought of making a vessel tight and strong out of strips of wood bound together with hoops? And when did he live?

No history of inventions, none of the encyclopedias in our great libraries, no historian of human progress, so far as we know, give any information on the subject, unless we accept the roman author Pliny, who mistakenly attributes the invention to the Gauls who inhabited the banks of the Po. We say mistakenly, since there is the best of good reason for believing that the barrel was in use long before the Gauls took possession of their Italian home, perhaps long before the Gauls existed as a people.

The monuments of Egypt furnish proof of the early use of hooped vessels, though no date is given of their invention. In one of the inscriptions copied by Wilkinson may be seen two slaves emptying grain from a wooden vessel made with hoops, while a scribe keeps tally, and a sweeper stands by with a broom to sweep up the scattered kernels. Close by an unfortunate is undergoing punishment by bastinado, for short measure perhaps, or, as Mr. Wilkinson suggests, for petty theft. The measure is barrel-shaped, and precisely like the *kayl* of modern Egypt. It would hold, apparently, about a peck. Unfortunately the age of this inscription is not indicated. Measures of the sort would seem to have been in common use very early in Egypt, though not for the storing of liquids, for which purpose skins and earthen vessels were employed.

At first thought, Egypt would be the last place to look for the invention of hooped vessels, its arid climate making it specially unsuited for their employment. Possibly, however, that may have been the compelling cause of their invention.

Throughout the East, the bamboo is largely used for making hollow vessels, a section of the stem through a node securing a solid bottom, and one between the nodes an open mouth for a natural tub or bucket. In well wooded regions, nothing would be more natural than the employment of hollow tree trunks for the same purpose, or sections of tree stems, hollowed out by fire or otherwise. In drying, such vessels would split and spoil, and it would require no great genius to repair them by means of withe or wooden bands, the primitive form of the hoop.

If the users of such natural barrels should migrate to a region where timber was scarce, economy of lumber would be likely to suggest the building of barrels from pieces artificially split, in short, the use of staves, by means of which the primitive cooper would be able to make several barrels out of a block that would suffice but for a single dug out.

But this is speculation merely. It is enough to know for a certainty that the cooper's art, like the potter's, is one of extreme antiquity. We had no suspicion of its venerableness when we began to trace its history in response to the inquiry—who made the first barrel?—*Sci. Am.*

Movable Propeller for Sailing Ships.

This new propeller, designed for occasional use on sailing ships, was first shown at the recent maritime exhibition, Paris. As sailing vessels in our coastwise marine now frequently carry a small steam engine for handling the cargo, the idea of employing a propeller to be used in calm, against head-wind, or as occasion demands, would seem available were it not for the fact that a fixed propeller would only be a drag when not in use. This apparatus is designed to overcome this objection. It consists of an iron frame hung on hinged arms at the stern, and bearing in the centre an upright shaft. At the lower end of the frame work are two toothed wheels for transmitting the motion of the shaft to a short propeller shaft hung below. At the top of the upright shaft is a horizontal grooved wheel for a belt that extends inboard to a wheel connected with the engine. When ready for work, the apparatus hangs partially submerged just behind the rudder, and, by means of the belt, the propeller is readily turned and the vessel moved. When the ship is under sail the belt is thrown off, and by the aid of a hand windlass on the deck, the whole apparatus is lifted out of the water, and may be secured to the edge of the rail, just where the ship's boat commonly hangs. The apparatus may be lowered and put in order in less than five minutes, and in escaping calms, navigating crooked rivers and canals and against light head-winds, will, in the opinion of marine experts who have examined it, prove of great value.—*Scribner.*

THE STEEL BUSINESS OVERDONE.—The manufacturing capabilities of the world in regard to steel appear to be very much in advance of the present demand for that article. Following is a memorandum of the various manufacturing now engaged in this production: Great Britain has now 21 Bessemer steel works, with 105 converters; Prussia, 14, with 61 converters; Austria, 12, with 30 converters; Bavaria, 2, with 4 converters; Alsace, 1, with 2 converters; France, 8, with 25 converters; and United States, 8, with 26 converters. These figures represent an aggregate of 67 works, with 247 converters, whose annual productive power is 2,460,000 tons.

MOKEE, of the St. Louis *Globe-Democrat*, has been convicted of complicity in the whisky frauds.

The Mining Share Market.

The mining share market has not been very active this week, and for several days a depression has been manifest. On Wednesday and Thursday stocks were "off" considerably, as our stock tables show. Prices have by no means been maintained at the figures expected by the hopeful ones, although the reports from the mines continue good. Mining development goes steadily ahead all along the Comstock range. The great bonanza at the north end shows richer and more extensive, and valuable developments are being made in the Imperial, Bullion, Yellow Jacket, Belcher, Overman and other mines of the south end. Throughout the great, broad mineral belt, new prospecting mines are being started into operation daily, regardless of the present severely adverse state of the weather, and when spring and the regular mining season fairly opens, an era of prosperity will be inaugurated never before seen in the history of old Washoe.

On Wednesday morning reports were current upon the streets that Savage had struck a stream of water which had filled the mine for a depth of over four hundred feet, the finding of which is generally regarded as a most favorable omen by those seeking for ore. These rumors proved to a certain extent true, and when the office of the company was opened in the morning a dispatch was found to be on file, reading: "Large quantity of water coming in from the north drift, 2200 level. Has risen to near 2000 level." This, to the holders of Savage who had been long waiting for a good "rise" in the stock, was a damper to their feelings, and again were their expectations blasted. The striking of water is regarded by experienced miners as a very good indication of finding ore, and when the mine is drained of it, it may prove that it came from the ore body.

The Alps mining company, in Ely district, has announced its first dividend, as will be seen by our Shareholders' Directory.

We give in this issue a new table, showing the highest and lowest prices of mining stocks in January, and also for the past week, which we will hereafter publish weekly, corrected to date for the convenience of our readers.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

ADVANCE.—*Alpine Chronicle*, Jan. 27: The stock of this company is selling at \$4.25 in the San Francisco Stock Board. The company has set apart forty thousand shares as a working capital, and upon the sale of this stock the mine is being worked. The stock is not assessable, therefore purchasers have nothing to pay in this respect, and as a consequence the majority of the stock already sold is in the hands of responsible parties in San Francisco, who are holding it as a safe investment, and not for stock-jobbing purposes, their knowledge of the management of the mine, and the flattering assays obtained from the drillings of the diamond drill in sinking, being incentives to their investments. We can assure those interested in the Advance that the mine is being worked economically as well as systematically. In sinking work has been erected, and the shaft is seven by seventeen feet in the compartments, and is down about eighty feet, the sinking having been done by hand while the steam hoisting works were being placed in position. The drillings from the diamond drill, obtained at a depth of 100 to 200 feet, assayed all the way from \$153 to \$250—made by Strong & Co., of San Francisco. The shaft is being blasted to the depth of 150 feet, upon the completion of which drilling will be resumed to the depth of another 150 feet. It is thought that when the 150-ft level is reached, a good body of paying ore will be laid open, and with the Fryer process, which is said to be eminently successful in reducing rebellious ores, the mine can be made to pay its way to a greater development.

AMADOR.

FIRE EXTINGUISHED.—*Amador Ledger*, Jan. 29: It is a relief to state that the fire which has been smoldering in the Amador Consolidated mine of Sutter Creek is out. For three days last week water was turned into the shaft from the Amador canal, until it reached the drifts where the fire was thought to have taken a tenacious hold. On Friday the shafts were opened and the fire found to be extinguished. The miners who were still in town were notified to return to work. It is the intention to keep the mill running on rock taken from the upper levels of the mine, which have not been touched either by fire or water. No ore has been extracted as yet owing to the presence of bad air. As soon as this difficulty can be overcome the mill will start. The water is being taken from the shaft as rapidly as possible. No time will be lost in freeing the mine from water, but it is estimated that one month at least must elapse before the water can be disposed of. The amount of damage done it is of course impossible to tell.

IN PAY DIRT.—*Trueb & Bellard*, who for two years have been running a tunnel on the Montreal placer claim, have struck the main channel of pay dirt at a distance of 1,050 feet from the mouth of the tunnel. They will commence washing in a few days. The appearance of the pay dirt indicates that the day of recompense for the expenditure of muscle and coin during the past two years is about to dawn.

VOLUNTARY MINE.—The mill in connection with this mine has been idle for several weeks owing to the roads being in too bad a condition to admit of hauling rock from the mine. The prosecution of work in the mine is greatly retarded by the flow of surface water. It is not anticipated that much will be done in the way of crushing until the weather becomes more settled and the roads improve.

A SPLENDID YIELD.—Mr. Pine's small five-stamp mill near West Point bridge was kept running for five days last week on rock taken from his own mine. The clean-up yielded \$1,600, an average of \$30 daily to each stamp. There is plenty more rock of the same character both on the dump and in the mine.

CALAVERAS.

RICH QUARTZ DISCOVERY.—*Calaveras Chronicle*, Jan. 29: We learn that some very rich quartz has recently

been discovered in the vicinity of Latimer's old store, near Central Hill. As yet prospecting has been confined to several narrow "spurs" or "striations" from a large vein which lies in their immediate neighborhood. Rock of unexampled richness has been discovered, in some places the veins showing more gold than quartz. Should the main ledge develop anything like what its offshoots indicate it will prove to be the richest thing in the country.

EWING MINE.—The work of running the 1100-ft level in the Ewing mine is progressing as fast as a full force of hands can drive it. The ledge has already been struck—showing low grade ore, however, as yet—and it is expected that in a short time everything will be in readiness for opening stopes. It has invariably been the case, in all the levels run, that the chimney, when first struck south of the shaft, has shown poor rock; but as the levels progressed the ore increased in richness. In the 1100-ft level the ore has been struck nearer the shaft than in any of the upper ones, and the prospects are flattering that the "lift" will prove extensive and rich. The battery has ceased operations temporarily, the cave of a couple of weeks since having prevented work in the stopes from the 1000-ft level. As soon as the 1100-ft stopes can be opened, however, the stamps will be in motion, and there will be no further difficulty in keeping them constantly employed.

INYO.

DARWIN ITEMS.—During the past week work has been pushed in all the different openings of the Defiance mine, and in every place the quantity and quality of the ore is constantly improving. The "bonanza" in the middle ledge is looking better than ever, but no definite idea of its great extent can yet be formed. The south chimney on the second level looks equally as well, and promises to be just as extensive as that on the middle ledge. We have been about the receipt of live assays of ore taken from the lower levels, which were made on Tuesday last, and it is certainly very satisfactory, showing an average value of \$164.85 per ton and in lead 63 per cent. This kind of ore will produce bullion, allowing for all losses, of about \$500 per ton value. Since the above report was written, P. Reddy, Esq., returned from San Francisco, and informs that having been purchased by the Defiance mine, the company and will be forwarded and erected at once. The works will be run by a donkey steam engine, and are capable of raising ore from a depth of 600 ft. Also, that ore scales have been purchased capable of weighing 20 tons.

DEFIANCE FURNACE.—In consequence of the non-delivery of coal the Defiance furnace was compelled to shut down on last night. It is to be regretted, for it was the wish of the superintendent to ascertain how long an uninterrupted run could be made. As it is, the furnace has run thirty-three days constantly. The shipments since our last issue embrace 684 bars. The total amount, in pounds, shipped since the furnace started is 259,289, and there is a small lot still on hand. Arrangements are now being made for a full and constant supply of coal, and the furnace will soon enter upon a better and more profitable career than ever.

QUEVEDO FURNACE.—This furnace has been running, since our last report, with some slight interruptions, which are always incident to the starting of a furnace. The obstacles are being overcome, and the furnace is now doing quite well. Since starting, the furnace has burned all the anthracite gravel deposit extending from Spring creek to the road leading from Chokechilly to Backbone house and Lake City, and including all the old town site of Columbia Hill. This mine is one of the largest structures of the kind to be found in this part of the State, it being eight feet wide, thirty inches deep, and on a grade of five and three-eighths inches to the foot, requiring over 400,000 feet of 10-inch brick to line it, although a portion is lined with rocks, which seem to run as well as the blocked portions. They are now washing a large portion of the deposits of tailings run from top ground into the ravine adjoining the side hill, which they are now sweeping into this enormous gateway for tailings. They now have a bank of 80 to 100 feet, which grows deeper and deeper as they continue up the side hill, reaching to the depth of 250 feet above grade, before they get to the top of the ground. This mine covers an area of over 1,000 acres of ground, which it is estimated will take from ten to fifteen years to run off with the most approved appliances and machinery for working these immense deposits.

CALIFORNIA MINE.—The Gaston Ridge ledge, owned by Sberiff & Co., of San Francisco, and owned by McDonald, and known as the California mine, is looking splendidly now. The ledge is large, the rock is very rich, and there are about 40 men now employed. Our informant thinks the mine will prove one of the best in the county. The mill has eight stamps, which are kept constantly running on rock taken out of the mine. A large amount of dead work has been done with a view of opening the mine properly. The rock has been assayed, and the expenses and left a dividend besides. In short time the owners intend to enlarge the mill, and work double the present quantity of rock, when the returns are expected to be equal to any mine in the county.

THE MANZANITA MINING COMPANY have been working their claim night and day. The ground is looking first-rate and a big clean-up may be expected. The gold dust begins to come in, and there is plenty of coin at the Bank of Nevada County to buy all that is offered. No one would imagine that coin was scarce after looking at the trays at the bank.

PLACER. **ANOTHER BLAST.**—*Dutch Flat Forum*, Jan. 29: A fine blast of 345 kegs of powder was set off at the Yankee claim yesterday, which was said by experienced miners to be one of the best and most effective they had ever witnessed. The end of the tunnel from which the gold drifts were taken was in 105 feet, from which the drifts were reached, and the rock was blasted to a depth of 100 feet. At 10 o'clock, everything being in readiness, Col. Ludlum had the wires attached to the battery and gave orders for the fuses to be lit, (the superintendent always puts in fuses to make a sure go of it, provided the battery does not work) and as soon as the men could get out of the way the battery was fired, and the blast was heard, and a half a minute later the finest scene that could be witnessed in a lifetime. The earth for the space of about two hundred feet square rose, as if by the hand of magic, to a height of about ten feet, then fell back a crumbled and mixed mass of blue gravel, cement and clay. The sight was beautiful, and the effect was a fact that could be desired and expected by the hotel, or the careful, well skilled men who bossed the work. This blast has loosened sufficient dirt to make one good run.

DRYER.—*Auburn Herald*: When the Auburn gravel mining and ditch company began their project, which contemplated using 500 inches of the water which comes down the Bear river ditch, for mining purposes, the farmers in this section and a few outside farmers, who were not in the ditch for agricultural purposes. It is now proven that their fears were unfounded, as the Auburn mining company has for over a week been using 600 inches of water in their mine, and yet the farmers, according to their own story, have plenty.

PLUMAS.

THE FRANKLIN.—*Plumas National*, Jan. 27: The work on the shaft belonging to this company, on Willow creek, has suspended temporarily, the water having proven too strong for the machinery now in use. The company held a meeting at this place on Tuesday, and concluded to make arrangements for a large boiler which has been used by the North Fork company at Ohio Flat. As soon as it can be put in position at the shaft, work will be resumed. The indications are plentiful that blue gravel is close at hand.

SAN BENITO.

THE STATION QUICKSILVER MINE.—*San Benito Advance*, Jan. 27: We learn that arrangements are in progress by an English company for the purchase of the Station quicksilver mine, but the trade is not yet consummated. The price agreed upon is \$250,000, a small amount for the size and equipments of the district. Bob says when he gets the money he will consider it a sale. In the mean time his men are getting on ore rich in mineral, from which he expects to make his pile, sale or no sale.

SISKIYOU.

MINING IN THE KLAMATH.—*Yreka Journal*, Jan. 27: Mining operations in the Klamath at and near Hamburg bar, below the mouth of Scott river, are being carried on very extensively and successfully, and more gold will be taken from that section this year than during any previous one. Kittlewood & Co. took out over 108 ounces last week, and will probably take out over \$200,000 of gold this season. The rise in the price of winter storms. Bean & Co. are almost ready to take out the pay gravel and have been taking out some gold already. They crowded the river over on the opposite bank, so as to be sure of getting in the old channel, and were considerably beyond the channel sought, otherwise they would have been in the pay gravel some weeks ago. Learned & Co. are also nearly ready to get out the pay gravel from the river bed, and rich reports may soon be expected from their claim.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, Jan. 27: Daily yield, 600 tons of ore. The entire mine is simply looking splendidly, and is giving renewed promise day after day of richer and greater bodies of ore to uncover in the lower levels than have yet been opened in any portion of the mine already prospected. The mills are all kept steadily running, notwithstanding the fearfully stormy state of the weather and had condition of the roads, and the yield for the month will reach and perhaps exceed \$1,800,000. The broken spur wheel of the new California mill has been replaced, and one of the batteries was started up yesterday morning, everything working finely. The other half went into full operation this morning. This will add a crushing capacity of 280 to 300 tons per day to that already employed.

JULIA.—The main southwest drift on the 1400 ft level is pushed steadily ahead, having passed entirely through the hard belt of porphyry into quartz of a very fine character. The drift is south, following the streak of ore first encountered on the 1500-ft level, shows the strata to be about 12 ft in width. The face of the main southwest drift, on the 1500-ft level of the mine, is in a tough, heavy body of clay, strongly resembling the east wall of the Comstock vein in the Bullion and other mines. This clay body is full of cross-slips, and contains spots of fine white pulverized silica in considerable quantities, which, when struck with the pick, will almost instantly give way and run down like sand.

OPHIR.—Daily yield, 100 tons of ore. This ore is being extracted from the 1500 and 1600 ft levels. Only one mill is yet running on ore from the mine, but another, the Winfield, will be added in a very few days more. The repairs to the lower levels of the mine are progressing at all points as fast as it is possible for such work to be accomplished.

AMAZON AND GLASGOW.—The cross drift on the third station level is in a distance of 38 feet, at which point the east clay wall of the ledge was passed through and a fine vein of soft white ore encountered, highly charged with sulphurets of silver. The ore vein at this point has every appearance of being of great width, and will undoubtedly take some time to reach the west wall. On the levels above the pitch of the ore vein was to the west, but on this level, a depth of 469 feet below the croppings, the pitch of the ledge is strongly to the east, showing the ledge to be a true fissure, having the regular Comstock dip.

BELCHER.—Daily yield, 450 tons of ore. The ore stopes are all looking splendidly, and still runs high in gold. The mills are all kept steadily running on ore from the mine, and the yield of bullion for the month will fully equal, if not excel, that of last month.

NORTH CONSOLIDATED VIRGINIA.—Opening the 630-ft station is making excellent progress, the excavation being in 30 feet this morning, in perfectly dry ground. The mill is already taking some time to reach the west wall. On the levels above the pitch of the ore vein was to the west, but on this level, a depth of 469 feet below the croppings, the pitch of the ledge is strongly to the east, showing the ledge to be a true fissure, having the regular Comstock dip.

IMPERIAL-EMPIRE.—Daily yield, 20 to 25 tons of ore. This section is in the yield is showing entirely to the inability of the teams to haul the ore to the level. The ore breaks are looking well both north and south on the 1930-ft level.

LEO.—The face of the south drift from the bottom of the winze, 200 feet below the tunnel level, is in good milling ore. The east cross-cut on the same level is also in fair ore.

EMPIRE.—Judging from the general stratification in the present level, the width of the vein fissure will prove much wider than is figured upon, and important developments at a greater depth may be looked for.

BULLION.—The northeast drift on the 2000-ft level of the Imperial shaft is making the usual good progress, the face of the effort, cast running ground, interspersed with streaks of stringers, is lively looking quartz. The north drift on the 1700-ft level of the Imperial is steadily advancing, still following the west wall of the ore vein.

CALIFORNIA.—Sinking the C. & C. shaft is making steady and favorable progress, the bottom in good working ground. It is now down 1020 ft. The north drift on the 850-ft level is steadily advancing, the face still in ore of a very rich quality. This drift will connect to-day with the bottom of the winze being sunk below cross-cut No. 5 from the north drift on the 1050-ft level. This is about all the prospecting that is being done in the mine at present, and about all that can be added is, that the entire mine was never before in such a good condition as it is now.

YELLOW JACKET.—A cross-cut has been started east from the bottom of the south winze on the 1940-ft level, which is steadily advancing at a very favorable rate of speed.

LADY BRYAN.—Sinking the main shaft is making steady progress, the bottom still in ore giving good assays. The south drift on the 850-ft level is opening up finely.

SILVER OTTY.—Since last week's regular report a raise has been started about 300 ft from the mouth of the main adit tunnel, which is to-day some 25 ft above the track floor, and the top of it is in high grade ore. It will be pushed through to a connection with the ore stopes, and will undoubtedly take some time to reach the shaft or outlet for the ore from the stopes. A large amount of rich ore is accumulating on the dump.

SERRA NEVADA.—Sinking the new shaft is making excellent progress, the bottom in good working ground. The west drift at the 1260-ft station is making splendid progress.

KOSUTH.—The main south drift on the 850-ft level is steadily advancing to the southward, the face in a fine quality of white quartz and low grade ore. The north and south drifts from the main west cross-cut on the 600-ft level are steadily advancing along the ledge, for the purpose of draining the water before attempting to cross-cut the ledge.

BUCKETT.—The incline is sunk to a depth of about 7 ft below the 650-ft station, and will be continued far enough to make a 12-ft sump, or well room for water. To-morrow a main drift will be started for the ledge from this station. A large amount of water has been met with at the bottom of the incline thus far, but the pump now handles it with ease.

WEBSTER.—This mine is located just south of and adjoining the Kosuth. The croppings are large and the surface indications are excellent. A good working shaft is being sunk, and a fine, commodious hoisting works building, blacksmith and carpenter shops are being erected.

DATRON.—The north and south drifts on the 500-ft level are steadily advancing, each running parallel with the ore vein. The south drift on the third station level is also steadily advancing toward the Kosuth line.

LADY WASHINGTON.—The cutting out and timbering for the tank at the 530-ft station is completed, and the tank is now in progress of construction. Meanwhile, the pump sections for the second plunger are being lowered into position.

ETROPA.—Work has been suspended in both the north and south drifts on the 320-ft level almost the entire week, pending some necessary repairs to the hoisting machinery.

SALE & NONCHES.—Sinking the north winze below the 240-ft level 100 ft north of the incline is making steady progress, the bottom in ledge material; it is now down 40 ft.

BEST & BELCHER.—After the extraction of water from the 1700-ft level the double winze connecting the 1500 and 1700-ft levels was found to have caved somewhat. The winze is now being thoroughly repaired and put in good working order preparatory to resuming work in the drifts on the lower levels.

CROWN POINT.—Daily yield, 350 tons of ore. The decrease in the yield is principally owing to the inability of the haulers to get it to the mills. There is no change in any of the ore-producing sections of the mine.

CALIFORNIA.—The pump bobs are in and ready to run at the 400-ft level, and the excavation for the pump station at the 800-ft level is nearly finished.

SILVER HILL.—The flow of water is gradually slackening in the face of the east drift on the fourth level, while it appears to increase in the bottom of the main incline. It begins to look as if the incline was draining the water from the level above.

MINN.—The putting in of stations and a ladder-way for the escape of men from the mine is making good progress. The shaft is now down 1,006 ft.

UNION CONA.—The south cross-drift from the upper tunnel is showing very fine and encouraging quartz and ledge material in the face.

GOULD & CURRY.—The repairs to the shaft are making steady progress. The water is drained from the 190-ft level, and it will not now be long before everything in and about the mine will again be in good running order, and prospecting resumed on the lower levels.

CHOLLAR POTOM.—Daily yield, 50 tons of ore. The south prospecting drifts on the 1250 and 1350-ft levels are steadily advancing. Sinking the new combination shaft is making excellent progress.

NEW YORK CONSOLIDATED.—The east and west prospecting drifts on the 800-ft level are both steadily advancing, in very favorable ledge material.

MEXICAN.—Work has been resumed on the 1455-ft level of the Ophir shaft. The winze below this level is being crowded steadily downward, the bottom in quartz and ore of a very hopeful character.

ORIGINAL GOLD HILL.—Ore extraction at the rate of 20 tons per day is going forward, the south ore body holding out and showing splendidly in the bread and stopes, as well as the raise in the north end of the body.

JUSTICE.—Nothing new in the ore stopes and breasts at the 400 and 600-ft levels; yielding as usual.

SOUTHERN COMSTOCK.—The cross-cut is now in 845 ft, with the face in very favorable vein material.

ROCKY MOUNTAIN.—Cross-cut has been started to determine the width and character of the ledge on the 650-ft level.

SAVAGE.—Opening the prospecting drifts on the 2000 and 2200-ft levels is steadily progressing.

SUPERIOR.—Situated in Crown Point ravine. Sinking a three-compartment working shaft, which is now down 18 ft.

SUCCESS.—The north prospecting drifts on the 550-ft level are steadily advancing, the ore and quartz in the face of the west drift showing favorable improvement.

COSMOPOLITAN.—Face of main north tunnel and the winze below the tunnel level, following the ledge, showing splendidly in ore which gives good assays.

EMPIRE.—Face of upper tunnel is a hard break of porphyry at present. Diamond drill now down 400 ft, and evidently nearing the east wall of the ledge.

NEVADA.—Main drift north in the ledge advancing well and showing well in low grade ore in its face, with streaks of porphyry, clay and quartz.

KNICKERBOCKER.—The pumps are kept steadily draining the flow of water, without showing signs of cessation, is still strong.

ELY DISTRICT.

REVIEW OF OPERATIONS.—*Ploche Record*, Jan. 23: During the past week mining matters have taken a start that will prove to outside camps and to San Francisco that Ploche is still in the field, steady and staunch. The development of the mine will have a tendency to immediately start prospecting in the mines over the Divide, such as the Portland, Excelsior and others, in addition to which there are numerous mines not known to us by name that the owners will now be anxious to develop, and will use their best endeavors to do. The bullion shipments during the past week have amounted to \$45,512, a large increase over an previous week for nearly a year. The Raymond and Ely mine has made a rich strike on the 1000-ft level, and have pumped their shaft dry, so that sinking is now progressing rapidly. Piochers can now congratulate themselves that the worst of matters are about over, and that Ploche from this time forth will show itself as being the second camp in the State of Nevada.

The past week's development of the mine have been made in the Alps mine. In the cross-cut on the 160-ft level an important strike has been made, consisting of a gold quartz ledge of a width of two feet, the quartz on being pulverized showing fine specimens of free gold. Assays of this ledge show it to be worth \$7,385.07 per ton. Outside of this development work is being done on other portions of the mine night and day, and fine ore is being hoisted to the surface and shipped to the Floral mill to the amount of about twelve to fifteen tons daily. Mr. Blair is at present laying aside the gold quartz from the cross-cut, as the mill has all it can do to work the other ore extracted daily.

Pulp assays \$140.—On Monday night the pump of the Raymond & Ely mine succeeded in draining the shaft dry, so that on Tuesday extra pump rods were placed in position and sinking was commenced again with extraordinary vigor. Since that time the pump has kept the shaft in a dry state so that the progress in the work of sinking is not interfered with, and before long we are in hopes of chronicling a fine development of ore below the water level. A very rich strike was made on the 1000-ft level, which grew better daily.

In the Meadow Valley mine there is no general change to report. The work continues as usual on the 1200-ft

Silver Coin.

The enormous yield of the bonanza mines, and the certainty that they will be made to produce so many millions of dollars in silver monthly, and that the nature of money compels the owners of it to seek or create opportunities at once for its active and constant employment, makes the status of silver, as a commercial factor, an interesting subject. Gold being the standard, the price for refined silver is regulated in the United States by quotations from the London market, and Congress has vested authority in the Secretary of the Treasury to dictate what rates shall be paid at the mints. The current price is \$1.20½ per ounce. The action of Germany in demonetizing silver had the effect of diminishing its value considerably. If Senator Sargent's bill to make it equal to gold for any payment not exceeding twenty dollars should become a law, as it ought to, its ultimate effect will be the creation of a vigorous demand at home that will serve as a good outlet for any surplus.

If in the daily commercial transactions of our 40,000,000 of population one person in twenty-five should use twenty dollars in silver, and each twenty dollars were made to do quadruple duty in passing from hand to hand, it would require \$50,000,000 to meet the demand for constant circulation. The probability is that three times that sum will be thus used in the United States when the provisions of the act of Congress of 1873, as amended in 1875, providing for the redemption of the fractional currency in subsidiary silver coin, have been complied with. The fractional currency now afloat amounts to about \$32,000,000. The whole amount issued was \$50,000,000, but \$18,000,000 have already been retired and destroyed, and the Secretary of the Treasury, who was vested by the act of Congress with discretionary power, has already caused \$9,000,000 of the smaller silver coins to be hoarded at the mints preparatory to redeeming the remainder, which will no doubt all be retired as soon as the accumulations are sufficient for the purpose, and the currency conditions enable the Secretary to protect the Government against speculative combinations. If it be true that the \$10,000,000 in silver bullion proposed to be exhibited at the Centennial Exhibition, in proof of the wonderful monthly capacity of the famous Nevada mines, will be purchased by the Government, the fractional currency will probably be all called in at least a year sooner in consequence.

While the above estimate of \$150,000,000 in silver for current business transactions in the United States is a fair one, it may well be that double the amount will be used. The practice of hiding money is very widespread. It is common in Mexico, and is the notorious custom in India and China. The readiness with which France paid the indemnity of \$1,000,000,000 was owing in a great measure to this habit, and a little reflection will show that the exercise of it will prevent silver from ever becoming inordinately cheap, no matter how generously the bonanza mines may supply it. In China and India, for instance, there are 600,000,000 of population. Allowing four to a family there are 125,000,000 of families, and if each family hoards away only five dollars a year the annual disappearance in this manner would foot up \$625,000,000. This accounts naturally for the absorption of silver into the Orient, which so many writers have considered as a mysterious fact. Silver is held in high repute there. In 1864, during a financial crisis in Calcutta, it was found impossible to raise even a single rupee on \$100,000 in gold.

If Senator Sargent's bill, above referred to, becomes a law, and the condition of relative values justifies the Secretary of the Treasury in substituting subsidiary silver coin for the fractional currency at an early day, the whole country will be the gainer.

Sangre de Cristo and its Mines.

In the Sangre de Cristo range, about three miles north of Abeyta pass, are what are known as the Grayback diggings. There are at present several men at work, all of them working on one mine, the main lead of the camp.

This one lead is showing up very well now. A gentleman informs us that he was shown a specimen of quartz, claimed to be taken from it, that was really the finest gold bearing quartz he had seen in Colorado. It showed great pieces of scale gold all over it.

These mines are among the oldest in this part of the Territory. They were worked by the soldiers a number of years ago. They have not been developed, however, to any great extent. But as they now seem to be showing up more encouragingly, there is hope of the place becoming quite a camp.

Not far distant from the above mines are some placer claims which a few men have persistently worked for several years. They have steadily taken out gold, but on account of lack of water and other facilities, it has been in rather small quantities, not reaching a maximum of more than two dollars and a half per day. But, knowing that the gold is there, they still work.

A ditch has been run from the Sangre de Cristo creek, in Abeyta pass, to supply them with water. It is a number of miles in length, and quite a herculean task for a handful of miners to undertake, but they expect to complete it in the spring, and then they will reap the reward of their perseverance and labor in the gold that will be taken out.

The mines above Mosca pass, near where

Mr. Bowman's mill has been erected, from all accounts are in a very prosperous condition. Those who have visited them lately, have been very much encouraged by their appearance, and a number have gone to work to develop their individual mines.

The mill is about ready to start, and unless the ice interferes will be started up, and a considerable quantity of ore milled before spring. Mr. Bowman has labored very persistently, and under great difficulties, and deserves success. His mill will be the means of either proving the district a failure, or else opening it up as a rich mining camp, and we look for the result of his labors with much anticipation, and hope and believe that the running of the mill will demonstrate this to be one of the best gold mining camps in the Territory.—*San Juan (Col.) Prospector.*

Bees in San Diego.

In the course of an able article describing the various interests of San Diego county, the *World* of January 8th prints the following paragraph concerning the honey interest:

The narrow canons and bleak hills of San Diego county that used to be held in derision by the upper country, have proven themselves to be productive of a wealth that places them fairly on a level with the agricultural portions of the State. No matter how steep the hillside, or how gloomy and dark the canon, the nimble winged bee in its busy search for the sweet stores that nature has hid within the bosom of the flower, regards it not, but flits from place to place and gathers its rich store, and lays it away for the benefit of its master, man. The business of bee culture has continued to increase with great rapidity, and in every instance when a person understands the business and will devote his time and attention to it, it has proven profitable.

The following table will show the increase in the business for the last four years:

Year.	No. of Hives
1872.....	1,136
1873.....	1,854
1874.....	2,493
1875.....	8,761

The yield of honey, while very fair, has not been as great as it would have been had the bees been allowed to work where they were swarmed, but a large number of our bee men devoted their attention to the production of bees rather than of honey, and the moving of the swarms to new localities, of course interfered with the working of the bees to a great extent, but notwithstanding these drawbacks, the yield of honey the past year will probably reach 400,000 pounds. Of this amount 307,000 pounds have already been shipped by steamer. There have been manufactured by our two planing mills 16,700 hives; there has been used 800,000 feet of lumber. In addition to this nearly 200,000 feet of cut lumber for hives and honey cases has been imported.

SMOKE PREVENTER.—A new fuel-saver and smoke preventer, as it is called, was first shown in public in Cincinnati the other day. The principle on which it acts is as follows: A current of air is forced by means of either a syphon or a fan through distributing pipes, three in number. The first of these pipes is located in front and under the grate bars, thus forcing the air through the grate. The second pipe is placed above the fire-door, blowing the air into the fire. The third is on the bridge wall, blowing the air forward. The three pipes combined entirely prevent the formation of smoke. It is claimed for this invention that it can be successfully applied to steamships, steamboats, locomotives and even to stoves.

A DISASTROUS EXPERIMENT.—That was a very foolish and disastrous experiment which S. K. Kidder of Iowa Hill tried last week. Kidder, says the *Placer Argus*, owned a valuable gravel mine near Iowa Hill and it seems that some one had been trying to rob the sluicines. In consequence the watchman had strict orders to shoot any one caught prowling around the premises. About two o'clock Kidder arose, and it is supposed went to the mine to see if the watchman was attending to his duty. It seems that he was, for the unfortunate man was shot through the head and instantly killed. Kidder was a man of middle age and leaves no family.

THE FIRST OF ITS KIND.—The legislature of Minnesota passed a law for the erection of a State inebriate asylum, the expenses of which are to be borne by a tax upon the liquor sellers. An appeal was made from the provisions of the law and the case taken to the supreme court, where its validity was confirmed. It is said that \$10,000 of the tax have already been collected, which it is expected will be increased to \$30,000 by the first of July. This is the first act of the kind, we believe, ever adopted by any of the States, and is well worthy of being introduced into every State in the union.

Rich copper deposits have been recently discovered in the Walker river section, about forty miles south and east of Virginia. The ledge is from five to twenty feet wide, and \$50,000 worth of ore has been already taken out. The ore is easily worked, and the cost of extracting it and getting it to market is but one cent a pound.

The direct exports of coal from Seattle during the year just closed aggregate for the three companies 70,157 tons. Of this quantity the Seattle company alone shipped 56,887 tons, the Renton company 10,456 tons, and the Talbot company 2,814 tons.

How Milk is Secreted.

In his address before the Pennsylvania dairy-men's association, Prof. L. B. Arnold gave a description and illustration of a fully developed udder in its active state, showing it to be divided into four separate glands, each acting independently of the other, but all bound together by elastic membranes and suspended and supported by one compound tendon connected with the abdominal muscles, and ramifying in minute filamentary divisions which fasten into every part of each division of the udder, and also into the skin which covers it, so that it is well supported, even when heavily laden with milk. Milk, he said, is not contained in the udder in one capacious sack, as many people suppose, and as some authors have represented, but in small reservoirs distributed through the glands. The largest of these reservoirs is at the top of the teat, which, as was shown by an illustration recently copied from a fully developed udder four weeks from the time of calving, was only about the size of a turkey's egg. The other cavities distributed through the glands varied from the size of a hickory nut to a pin-head, the largest and greatest number being located at and near the lower part of the udder, diminishing in number and size upward. The reservoirs in each quarter of the bag are cemented by a set of tubes distinct from the other quarter, which run like blood-vessels by crooked routes from one reservoir to another, till they at last connect with the larger cavity at the top of the teat. In each quarter of the udder all the internal arrangements and subdivisions of the glands are not only independent of but different from the corresponding divisions in the other quarters. The reservoirs and tubes in no two quarters are alike, either in size, location or number.

Tapestry.

In early English mansions the walls of apartments were usually covered with tapestry. In those days there were not so many broad plain surfaces on the walls, and the rooms were lower than now. There was more wood work; large ornamental fire-places, dados, cornices and window recesses occupied much of the walls, and they were often entirely or partly paneled in oak. The furniture was massive, while trophies of the chase and the battle-field held a prominent position, and tapestry completed the mural decoration. That the wall was beautifully painted seems probable, for the number of churches having mural paintings is so great that a list of such has been published by the science and art departments of South Kensington. These specimens of wall painting have been, for the most part, discovered under many coats of color after ages of neglect.

Tapestry weaving is said to have been introduced into England in the time of Henry VIII. by William Sheldon, who brought workmen from Flanders about 1540; but probably the art was merely revived at that period, for so early as 1302, Lord Arundel bequeathed to his wife Philippa the hangings in his hall recently made in London. However, tapestry seems to have been brought to great perfection in the middle of the sixteenth century, and about that time were not uncommon in the houses of the middle classes.

Stamped, painted and gilded leather has long been in use as a wall decoration. It is said to have been invented by the Spaniards, though introduced into England by the Flemings in the reign of Henry VIII.

The tunnel of the Virginia City and Gold Hill water company, near Marlette Lake, in the Sierra Nevada, will, when completed, be 5,000 feet long. At present work is being done on both ends of it, and a distance of 1,200 feet has been excavated. The progress is at the rate of sixty-five feet per week. The rock now is hard, but it is easy drifting compared with that which had to be done soon after starting at the western end of the tunnel. At this point a crevice in the rock five feet in width was struck, through which quicksand rushed with the rapidity and violence of water, completely filling up the tunnel, and it took sixty-eight days to get past this awkward little gap in the granite. At the eastern end a similar crevice was encountered, two feet and a half in width, which it took fifty days to pass.

It is stated that gold in large quantities has been found in Mariposa creek, about twelve miles above Placerville. A great many are engaged in placer mining there, and are averaging from four to five dollars per day, per man. It is thought this gold was brought down from the mountains by the late heavy rains, and that it comes from some rich mine which has never been discovered.

J. M. HITCHINGS, of Yosemite, has discovered in the headwaters of Kern river, 10,500 feet above the sea, a new and beautiful fish, which he named the "golden trout." Its color was like that of the gold fish, but richer, and dotted with black spots a quarter of an inch in diameter and has a black band along its sides.

EXTENSIVE preparations are being made to mine on Feather river, near Oroville, the coming summer, where it is known that gold exists in large quantities, the only difficulty in obtaining it thus far being that of keeping the mines free from water.

House Building.

One of the most readable articles in *Scribner's Magazine*, for January, is contributed by John Burroughs, who takes a very common sense view of the subject he discusses. He looks at the house also with the eye of the true artist, recognizing all the accessories to beauty contributed freely by nature, rocks, trees, hills, waters, and desires that in its construction and color it shall harmonize with these. He says: "If one's house existed for its own sake, if it were an end in and of itself, there might be some fitness in the attempt to give it positive beauty. But as the matter stands, only that human habitation satisfies my eye in which the aim of beauty or art as such is entirely swallowed up and lost sight of in the suggestion of comfort, warmth, stability, and I do not think that the house is beautiful, but inviting and home-like. If the builder has added any intrinsic ornaments, anything not in keeping with the necessities of the construction (of course I would not confine him to the bare bones of the case); if he has clapped on an abominable French roof, which, in our climate, answers so poorly the purposes of a roof, and suggests no shelter or hospitality; if he has thrust up a tower where there is no view to command; or if he has painted his structure one of those light, delicate tints, that is like nothing out of doors, and makes one feel as if the house ought to be taken in out of the wet and the weather. I see he has made a bid for the admiration of the public, and that he had no deep want in his heart to satisfy."

Further on, he says: "What is a man's house but his nest, and why should it not be nest-like both outside and in—coarse, strong, negative in tone externally, and snug and well feathered and modeled by the heart within? Why should he set on a hill, when he can command a nook under the hill or on its side? Why should it look like an observatory, when it is a conservatory and dormitory? The domestic spirit is quiet, informal, unceremonious, loves ease, privacy, low tones; the chimney corner, the old arm-chair, the undress garb, the homely cares, children, simple pleasure, etc.; and why should it, when it seeks to house itself from the weather, aim at the formal, the showy, the architectural, the external, the superfluous? Let state edifices look stately! but the private dwelling should express privacy and coziness. But every man's house is in some sort an effigy of himself. It is not the snails and shell-fish alone that excrete their tenements, but man as well. When you seriously build a house, you make public proclamation of your taste and manners, or your want of these. If the domestic instinct is strong in you, and if you have humility and simplicity, they will show very plainly in your dwelling; if you have the opposite of those, false pride or a petty ambition, or coldness and exclusiveness, they will show also. A man seldom builds better than he knows, when he assumes to know any thing about it."

Arizona Mining Items.

The Arizona *Citizen* has the following items: David Shultes was in Tucson last Saturday, from the Quacharty, where he is mining on quite a liberal scale for one of limited means. He is working at a depth of thirty-five feet, and is also having an incline run on a contract. In all he has sixteen men at work mining and now melting, at least he expects his blower from Phenix on his return. He hopes to soon increase his force to forty men. The mine looks well and every feature makes prosperous showing. Most of the ore shows horn silver.

Andrew Storrar has three men at work on the Sacaton—a galena and silver mine; and two men are taking rich gold ore from Ford's mine and are about ready to work it in arastra; miners are also opening up the Gray Eagle, as well as other mines in Quacharty district. A prosperous year is anticipated in that part of Pinal county.

Very favorable news has been lately received from the French mine. Discoveries of old works not hitherto known to the present claimants have been made, and the extent of valuable ore seems to enlarge as work progresses.

Mr. J. L. Darrah, one of the old mine claimants, recently returned from California, whither he had been to get married and attend to other very sensible business. He now goes to take charge of the old mine, which he regards as one of the best, notwithstanding his extensive mining experience.

We have no report from several districts this week, yet we know many men are at work with encouraging results.

We hear some little water was accumulated in the Santa Rita placers during the recent rains, and more will soon be, else all signs will fail.

The mining enterprises are as yet conducted mainly by men of muscle and determination to succeed and they will succeed, and have valuable property soon.

THE JUDN & CROSBY WORKS, since the burning of Stewart's mill, have had a full supply of ore and are producing as much bullion as the two works turned out previously. This shows that for the present there is enough room for only one custom works in that town (of the amalgamation class.) Two years hence two can find an abundance of material, but not now.—*Colorado Mining Review.*

THE Pensacola, Admiral Almy's flagship, has arrived here from a year's cruise.

USEFUL INFORMATION.

ANILINE PENCILS, COPYING PENCILS, ETC.—These new pencils are announced at the same time both in Paris and Berlin. The French pencils are made in Paris, according to the hardness, very much like common lead pencils. The materials used are aniline, graphite and kaolin, in different proportions. Made into a paste in cold water, they are pressed through a screen that divides the mass into the slender sticks used in filling the pencils. When dry the sticks are fitted to the wooden parts, and these are glued together very much in the usual way. They may be used in copying, marking in permanent color and in reproducing writing or designs. In copying, a thin sheet of moistened paper is laid over the letters, design or document, and the lines are traced with the pencils. The action of the water on the aniline gives a deep, fast tracing, resembling ink in color. The German makers also employ aniline in the manufacture of these pencils. On ordinary dry paper they give a well-defined mark that cannot be removed by india rubber. When the paper is dampened with water the markings assume the appearance of ink. These pencils may also be used for copying purposes, as when moistened sheets are laid over the writing, under a slight pressure, they will transfer good impressions that do not blur and that resemble the original in every respect. —*Scribner.*

MUCILAGE FOR MINERALS, ETC.—Mr. F. C. Hill, of the geological museum, Princeton, N. J., writes to the *Journal of Pharmacy* as follows: "My friend, Professor R. P. Whitfield, of Albany, N. Y., was good enough to give me the following recipe for macilage to mend fossils and minerals, and, after several months of experience with it in the museum, I find it so valuable that, with his permission, I send it for the benefit of the readers of your journal:

Starch.....2 dr.
White Sugar.....1 oz.
Gum Arabic.....2 dr.
Water.....q. s.

"Dissolve the gum, add the sugar, and boil until the starch is cooked. Professor Whitfield is in the habit of drying it into sheets, on paper, and re-dissolving when wanted. He does not claim to have originated the recipe, but thinks it is one of the compositions offered to the United States government for gumming stamps. It is certainly a very adhesive mucilage, and, owing to the sugar, never becomes brittle; so that it never scales off, as most glues do, from stones or other hard substances. In a geological cabinet it is simply invaluable."

PRESERVING OF HOPS.—A newly patented method of keeping hops employs carbonic acid as a preservative agent. Air tight, tin lined boxes are loosely filled with hops. Carbonic acid (made in a soda fountain machine by the usual sulphuric acid and marble dust process) is then admitted to the box through a tube that reaches to the bottom. The gas fills the box, driving the air out before it as it rises from the bottom. The hops are then compressed, and more filled in with an additional supply of gas. This is repeated till the box is loaded with pressed hops saturated with carbonic acid. The cover is put on, and more gas is added under pressure to drive out the last trace of air, and then the box is quickly sealed hermetically. The first experiments in this direction proved entirely successful.

A RULE WORTH REMEMBERING.—Here is a rule which will hold good for all dates in the present century since 1852, as well as for those in the present year. In order to find out the day of the week upon which any event fell one hundred years ago, count forward two days from the day of the week upon which the Centennial anniversary falls. For instance, the 4th of July, 1876, will fall on Tuesday; the 4th of July, 1776, was Thursday. The Centennial anniversary of the battle of Bunker Hill was celebrated Thursday, June 17th, 1875. The battle was fought Saturday, June 17th, 1775. This rule must not be used for dates in the eighteenth century earlier than 1752, because that was the year when the change from "old style" took effect in England and her colonies.

CLEANING WATER MAINS.—It frequently happens in iron water mains that deposits of rust are formed, sufficiently thick to reduce materially the diameter of the pipe. To clean the interior, Mr. E. Dodds, an English engineer, has lately devised a pipe scraper, which operates as follows: The pipe is cut, the scraper is inserted, temporary joints are made, and the water is turned on at highest pressure, which drives the scraper on at great speed. In the first experiment, a distance of 300 yards of pipe was thoroughly cleaned in two minutes and 20 seconds.

THE EAR OF A FISH, almost always entirely within the cranium, on the side of the brain, consists essentially of a vestibule and three semi-circular canals, which receive the vibrations of the integuments and cranial walls; there is rarely anything that can be called an external ear, drum, or tympanic cavity; loud, sudden, and strange sounds frighten fish; in ancient, and even in modern times, they have been taught to come and receive food at the tinkle of a bell, or the pronunciation of pet names.

An alloy for locomotive whistle which will give a clear sound is made of copper, eighty parts, tin, eighteen, antimony, two.

AIR COOLER. To reduce the temperature in a factory in Paris, recourse was had to an inexpensive form of air cooler. A thin plate of metal, perforated with holes one-tenth of an inch in diameter, and having a total area equal to one-ninth of the surface of the plate, was set at a slight angle in a tight box. Over this plate a thin sheet of water at a temperature of 55 Fahr. was allowed to flow steadily, and by means of a power blower air was forced into the box below the plate. By its pressure the air forced its way through the holes in the plate and through the water, and was then led by pipes to all parts of the factory. By this device, the air in the room was reduced to 57° Fahr., or within four degrees of the temperature of the water. Other experiments gave varying results according to the initial temperature of the water, but in each case the apparatus reduced the temperature of the current of air to within seven degrees of that of the water. Steam power is required for the blower, and, for the best results, the supply of water must be abundant and its temperature low. The application of this device might, in our warm climates, prove of use in pork packing and other industries where a low temperature is desirable. —*Scribner.*

POISONOUS POTATOES.—The sprouts of the potato when analyzed are found to contain a vegetable alkaloid called by chemists *solanine*, which is very poisonous. Solanine is obtained from various species of solanum genus of plants comprehending the potato, tomato, nightshade, etc. This alkaloid does not exist in the tubers unless they are exposed to the light and air. If potatoes remain for any length of time after having been dug too bright a light, or if the earth is accidentally removed from them in cultivation, they are changed by the chemical action of light and become green in color, which is owing to the presence of solanine. Potatoes of a blackish-green tint are good for seed, and it is claimed by some that the poison they contain is a sure preventive of decay, but they should never be cooked for the table. If they are boiled in a large quantity of water and the water carefully drained off, they may be fed to stock. —*Ec.*

OIL PAINT FOR FLOORS.—None but earth colors should be used in painting floors, and the rapid wearing off of a coating of oil paint on a floor is a sure indication that white lead has been mixed with the paint. This is generally the case, since it causes the paint to cover better and spread easier. Even the employment of a varnish that has been boiled with borate of manganese preferred. It is also very important that the first coating should be perfectly dry before a second is laid on.

WATER-PROOF DRESSING FOR LEATHER.—A dressing for rendering leather water-proof, made as follows, as proposed by Hager, has been found to answer the purpose: dissolve one part of india rubber in five parts of illuminating petroleum, by digestion for a day, and add twenty parts of paraffine to the paste mass and digest again for half a day, with repeated stirring, and then mix it with five parts of oil and five of tallow, and finally add ten of petroleum, or enough to give the mass the consistency of butter.

GOOD HEALTH.

VENTILATION OF CLOTHES CLOSETS.—Too little attention is paid in the construction of closets to their proper ventilation. It is not always convenient to have a closet door stand open, and if it were, full ventilation cannot be secured in this way. There should be a window or an opening of some sort from the closet to the outer air or to a hall, so that a current of air might remove any unpleasant odors arising from clothing that has been worn, from shoes, or from anything else kept in the closet. A garment that has hung for a length of time in a close closet is as unfit to wear, unless it has been thoroughly aired, as though the unwholesome vapors it had absorbed were visible to the eye. The charm of clothing new and clean lies far more in the absence of these vapors than many people are aware.

A WHISKY DIET.—The *Baltimore American* reports that the board of visitors of the jail in that city have assented to the testing of a novel and interesting experiment that is expected by those urging it to result in the radical cure of the insatiable thirst for strong drink. A number of the hardest cases, who yearn for the trial, are to be placed by themselves, and supplied with no article of food or drink that is not flavored with whisky. Coffee, bread, meat—in short, everything is to have a dash of whisky. It is believed that, in a few weeks, the tramps will become so disgusted that they will loathe the very sight of liquor, and thus cured of the degrading appetite, they may be restored to manhood, self respect and usefulness.

WHEN TO TAKE A WARM BATH.—A warm bath should be taken at night just before retiring, and if the system is weak the bed and sleeping room should be warm to prevent taking cold. Very few persons can take a warm bath in the daytime and go out into the air and attend to ordinary business without much peril.

Prevention of Chilblains.

MESSRS. EDITORS:—Appropriate to the season I send you a few lines for the "Good Health" column. As the minor miseries go very far to make up the grand total of human suffering, he who alleviates a single one of them does some good in his day and generation. Any one troubled with chilblains, which is no small grievance, who will pursue the following directions will find it worth a year's subscription to the *PRESS*.

Some thirty years ago a matronly old lady directed me, for this complaint, to put my feet into half a bucket of cold water containing a half ounce of borax dissolved therein.

The relief was very satisfactory, and three or four repetitions during the winter kept me completely free from the tormenting affliction. I afterwards omitted the borax and the result was the same. Should the plain water be too simple and cheap, one might put in five grains of morphia or ten drops of tincture of belladonna, or stramonium, or aconite, for their narcotic effect, or five grains each of acetate of lead and sulphate of zinc for their cooling and astringent effect, or a little hydrate of chloral (that's the fashion) for its—well, for some kind of an effect. None of these in small quantities will do any harm—nor any good. The water needs no adjunct; it will do the whole business.

The philosophy is this: Persons so afflicted are those of loose muscular fiber, and the cold water contracts the capillary vessels, and gives them tone to resist their engorgement. Where heart or lung disease exists the temperature of the water should not be below sixty deg. Fah.

Bingham, Utah.

POISONING BY A LAMP SHADE.—At a recent meeting of the medical society in Bonn, Professor Zuntz brought forward a case in which a gentleman who had for several years been subject to migraine observed that for some days he had headache late in the evening, which, without interfering with sleep, continued in the morning, and was accompanied with loss of appetite and malaise. In about a fortnight the symptoms became more severe and lasted the whole day. At the same time similar symptoms, but much less severe, appeared in two students who sat at the same table in the evening. The green shade of the petroleum lamp was suspected of being the cause of the mischief, and on chemical examination it was found to contain arsenic. Its use being discontinued all the symptoms ceased in the three individuals. It was evident that the heat of the lamp had set free the arsenic, and the greater severity of the symptoms in the first mentioned individual was due to the fact that he was near sighted, and therefore sat nearer the lamp than the others did. Professor Zuntz said that he himself was some years affected in a similar way, though less severely, while using a green lamp shade, in which arsenic was found.

DEATH FROM TIGHT LACING.—There has just died at Pimlico, Mrs. Kezia Wheeler, an old lady at the age of 77, on whom an inquest has been held. Mrs. Wheeler was found dead in her bedroom on Sunday morning last, dressed for church, and with her Bible in her hand, having apparently expired suddenly. The surgeon said death had resulted from the bursting of an aneurism, and the post-mortem examination revealed terrible evidences of tight lacing on the part of the deceased, who had been a very beautiful woman. In fact, one end of the old lady's ribs had been pressed against the internal organs, and had kept them constantly at half action, as it were, until apparently an aneurism was produced by the sudden rupture of which she died. Mrs. Wheeler must have been an exceptionally healthy woman to have thus lived in spite of the corset which imprisoned part of her organs and interfered with their natural development; had she not laced she would doubtless have been a centenarian. —*London Daily Telegraph.*

STARVED TO DEATH.—The *New Haven Journal* says: "A strange and painful fate was Police-man John Benson's, who died on Thursday in Norwich, at the age of sixty-eight. For three months he had suffered from a cancer on the tongue—possibly a result of too much smoking. For two months past the tongue has been so swollen and sore as to absolutely prevent all eating, and the sufferer was kept alive by semi-liquid food given by means of a tube. During the past ten or twelve days it has been almost impossible even to introduce this tube, so bad was the cancer growing, and for four or five days before his death the poor man was literally starving to death. The immediate cause of death was pronounced to be starvation. His relatives and friends, aware of the fate which was coming to him, stood powerless to avert it. Thousands will remember Mr. Benson as the excellent and efficient manager of the police every summer at the Willimantic camp-meetings."

CHAPPED HANDS.—The easiest and simplest remedy is found in every one's kitchen closet, and is nothing more than common starch. Reduce it to an impalpable powder, put it in a muslin bag, keep it in the table drawer. Whenever you take your hands out of dish water or suds, wipe them dry with a soft towel, and while yet damp shake the starch bag all over them and rub it in.

DOMESTIC ECONOMY.

Choice Treatment of Food.

In the choice of foods we cannot exercise too much care. It is cheaper to procure only the very best articles. All vegetables and fruits should be grown on the best soils, and the fertilizers used should be well decomposed and not fresh and rank. Partially decayed food of whatever kind should be avoided. For breads, the best white wheat is none too good. If grown in new soil it is likely to be better and to contain abundance of the mineral matter so needful to health. Fruits for eating without cooking should be ripe, tender and not too tart; while those for cooking may be either sweet or sour, but they must possess the peculiar quality of retaining when cooked their best flavors. Potatoes should be fresh and ripe—old ones are less wholesome, especially when they have been exposed to the light and air, and braised by much handling, or long exposed to cold.

Animal food should be chosen with great caution. Only healthy animals should be used for eating. They should be neither too old nor too young, too fat nor too lean. In butchering, all the blood should be removed from the body, as otherwise the flesh putrefies readily. It should be thoroughly cooled before eating. It is also desirable that the animal be not killed for several hours after eating or after fatigue. The long journeys animals are sent on crowded, filthy cars, render their flesh unwholesome.

The treatment of animal food is a matter of importance. Why do we cook it at all? First, to render it more pleasing to the sight; second, to develop its best flavor; and third, to render it digestible and palatable. Flesh cooked too much is rendered innutritious and indigestible; if cooked too little, it is disagreeable eating. Liebig said he would never have flesh subjected to a higher temperature than 170 degs. Fah., except for a few minutes after it is put into the pot, when it may be submitted to a temperature of boiling water in order to coagulate the albumen into a sort of crust on the outside to hold in the flavors that might otherwise be evaporated. In roasting meat, also, let the heat at first be high, and gradually decrease to the boiling point for the same reason. Stewed meats are more wholesome and nutritious than any other. The process renders flesh tender and succulent and easy of digestion.

The Origin of Pumpkin Pies.

The pumpkin pie is considered a parody American dainty, and ample justice is done it at each annual return of the holidays. It is to be hoped the institution will lose none of its patriotism and favor, and that the digestion of its lovers will not suffer when they discover that this specialty of the Yankee, in which he, or, more properly speaking, she—for the wife is the concocter—takes pride, is no American specialty after all, but existed in England two hundred years ago, and is to be found in "The Complete Cook," published in 1655.

The English pie is a much more elaborate affair than that of the Yankee, and contains more ingredients. As the season of good things is now at hand, when novelties of this kind generally prove acceptable, we give the recipe, which is so old, it can, like the dresses worn at the same period, be introduced to this generation and called new:

"To Make Pumpkin Pie.—Take about half a pound of pumpkin and stew it; a handful of thyme, a little rosemary, parsley, and sweet marjoram slipped off the stalk, and chop them small; then take cinnamon, nutmeg, pepper, and six cloves, and beat them; take ten eggs and beat them; then mix them and beat them altogether, and put in as much sugar as you think fit; then fry them like a froize; after it is fried let it stand till it be cold, then fill your pie; take sliced apples thin, round ways, and lay a row of the froize and layer of apples, with carraways betwixt them while your pie is filled, and put in a good deal of sweet butter before you close it; when the pie is baked, take six yolks of eggs and some white wine of verjuice (ver-juice,) and make a candio of this, but not too thick; cat up the lid and put it in; stir them well together until the eggs and pumpions be not perceived, and serve it up."

Now, any lady adventurous enough to try this pie can call it by a French name and give a dinner party to introduce it.

OATMEAL AND COCOANUT.—Oatmeal mixed with grated cocoanut produces a very attractive cake to both old and young. Take three heaping teaspoonfuls of grated cocoanut, or two of the prepared desiccated cocoanut; add to it half a pint of the finest oatmeal and two heaping teaspoonfuls of sugar; stir it into one gill of boiling water, and mix it thoroughly together; turn out on the rolling board, well floured, and roll it as thin and cut out as for common crackers; put a bit of citron and a half dozen currants into each cake, sticking them into the dough. Bake in a slow oven and watch carefully lest they brown a shade too deep. To make them crispy let them stand a day in an uncovered dish.

GRAHAM FLOUR PUTTS.—One quart of sweet milk, two eggs, flour to make in a thin batter, fill the gem cups two-thirds full, bake in a quick oven.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper, inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Feb 5, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Removal of Prominent Manufacturing Firms, 81. The Mining Season; Swindling Mining Companies; Direct Undercurrent for Hydraulic Mines; A California Bonanza, 88. Hydraulic Gold Mining in California; Straw Burning Engines; Hardware, 89. Notices of Recent Patents; General News Items, 92.

ILLUSTRATIONS.—The New Quarters of Fairbanks & Hutchinson, Parke & Lacy and F. Ogden, 81. Straw Burning Engine, 89.

SCIENTIFIC PROGRESS.—Science and Discovery; The Technology of Iron; The Relation of Battles to Storms; Distribution of Temperature on the Earth; Hydrated Cellulose; The Danks Furnace in England; Exhaustion of the Soil by Apple Trees, 83.

MECHANICAL PROGRESS.—The Screw Propeller—Old and New; Who Invented the Barrel? Movable Propeller for Sailing Ships; The Steel Business Overdone, 83.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 84-85.

MINING SUMMARY from various counties in California, Nevada, Colorado, Idaho, Oregon and Utah, 85-89.

USEFUL INFORMATION.—Aniline Pencils; Copying Pencils, Etc.; Mucilage for Minerals, Etc.; Preserving of Hops; A Rule Worth Remembering; Cleansing Water Mains; Air Cooler; Poisonous Potatoes; Oil Paint for Floors; Water-Proof Dressing for Leather, 87.

GOD HEALTH.—Ventilation of Clothes Closets; A Whisky Diet; When to Take a Warm Bath; Prevention of Ophthalmia; Poisoning by a Lamp Shade; Death from Tight Lacing; Starved to Death; Chapped Hands, 87.

DOMESTIC ECONOMY.—Choice Treatment of Food; The Origin of Pumpkin Pies; Oatmeal and Coconut; Graham Flour Puffs, 87.

MISCELLANEOUS.—Quicksilver Prospects in San Simon District; San Spots and the Grain Market; Pelican Mill; The Famous Mariposa Mill and Mine; The Osmestock; The San Diego Mines; The Franklin Claim; Star District; The Defiance Mine; The Golden Cities, 82. Silver Coin; Sangre de Cristo and its Mines; Bees in San Diego; Smoke of a Discretion Experiment; The First of its Kind; How Mill is Secreted; Rapidity; House Building; Arizona Mining Items, 86. Placer Mining Outlook; The English Channel Tunnel; Chinese Immigration, 94.

NEW ADVERTISEMENTS.

Miner and Hoisting Engines, Treadwell & Co., S. F.; Ore Crusher and Pulverizer, F. Alden, Pittsburgh, Pa.; Iron Pipe, Treadwell & Co., S. F.; Occidental Foundry, Steiger & Kerr, S. F.; Scroll Saws and Lathes, W. E. and John Barnes, Rockford, Ill.; Cherokee Flat Mining Company—Sale of Delinquent Stock; Eureka Stone Company—Assessment Notice.

On the Ophir mine the east drift on the 1100-foot level is steadily advancing, the face in quartz and low grade ore, the prospects becoming more and more encouraging as the drift advances. It will be remembered that this drift is running into the east country, and is in entirely virgin ground, all the former prospecting on the upper levels of the mine having been done to the westward of the shaft. The belief is steadily gaining ground that the drift will yet cut the top of a portion of the great bonanza ore body.

MESSES. DEFREES & CLARK have established works in this city for the manufacture of bicarbonate of soda from the native soda of Nevada. They have just turned out the first batch of a few tons, which the wholesale dealers in the article pronounce excellent. They propose making all sorts of chemicals in addition.

COINAGE.—The U. S. mint, in this city, made the following coinage in January: Gold—double eagles, \$1,940,000, 97,000 pieces. Silver—trade dollars, \$342,000, 342,000 pieces; dimes, \$275,000, 2,750,000 pieces. Total, \$3,617,000; 3,092,000 pieces. Grand total, \$2,557,000; pieces, 3,189,000.

The Mining Season.

Although the late heavy falls of snow in the mountains have been of great inconvenience to railroad operations, they are a cause of great congratulation to the miners. Throughout the gravel mining regions a copious supply of water has been running for nearly two months and this snow serves as a storehouse for a good supply for many months to come. The miners everywhere have a glorious prospect for a bountiful year. To a miner the great drifts and piles of snow are almost as good as piles of twenty dollar pieces, for few of them have any doubt about the ground in their operations. It all depends on a plentiful supply of water. The snow furnishes the water during the coming summer with which they are able to wash out the gold which has laid so long hidden under the gravel hills.

From all parts of the State we have expressions of satisfaction at the heavy fall of snow, and it is predicted by all that the season will be an unusually successful one to the hydraulic miners. In many places operations are enlarging and more gold being taken out than ever before. On the Klamath, in Siskiyou county, below the mouth of Scott river, a great many new claims are now being worked with success. The river is all taken up with mining claims for miles above Oak Bar, and a considerable distance below, and in a year or two more there will be more mining done on the Klamath than in any other mining district in that county.

In Butte county, where they are making a fuss over the decay of mining and the superiority of agricultural pursuits, the mines are doing well. The Oroville Mercury says that a steady stream of gold dust is pouring into the banking house of Rideout, Smith & Co., at that place, and into Wells, Fargo & Co.'s express office. Last year, owing to the small supply of water, not so much was received as formerly. The amounts taken at Wells, Fargo & Co.'s express office there during the three years past were as follows: In 1873, \$1,225,323 were taken in, in 1874, \$1,470,894, and in 1875, \$978,903, making a total of \$3,674,990. Last year the Spring Valley water company, at Cherokee, alone, sent down \$401,599.91, and this year it will take out a much larger amount of dust. On Friday last, while in the express office a few minutes, a large lot of dust came in from the Severance claim at Bidwell Bar. A small piece of bedrock was cleaned up and something over \$1,300 taken out. Small lots of dust were coming in every few minutes. On the whole, we think that more gold has already been sold here than during the whole of last winter.

Without doubt the gold product of California for the Centennial year will be such as to astonish the unbelievers who consider that the mining prosperity of the State is past and that agriculture must in future reign supreme. The miners are all hopeful and in high glee at the plentiful fall of snow, and will show some figures next year, as the result of this year's work, which will convince many that the California miner is by no means yet a thing of the past.

Swindling Mining Companies.

The Mendocino Dispatch thinks that some legislation is needed to curb the operations of swindling mining companies, and says:

"We think it highly important that an act to this effect should be passed. And we even think the Legislature should seriously consider the propriety for providing for the appointment of a Mining Commissioner, whose duty it shall be to unearth the rascalities of these assessment robbers and enforce fair dealing. A mining engineer of undoubted integrity might fill the place, and it should be part of his duties to visit and examine the location of wildcat mines and make public report of the work being done and their merit so far as opened."

The intention of the Dispatch is very good, no doubt, but we do not think the plan offered would be in the least effective in overcoming the evil. Several recent instances might be cited where a number of stockholders, directly interested, have endeavored to unearth supposed rascalities; but, whatever the reason may have been, the parties in power remain in power still, and the investigating stockholders got no satisfaction for their trouble. We must confess that we fail to see how any one man could follow up properly such managements as would be reported to him as dishonest, or attend to one-tenth of the business which such examinations would entail. Every time an assessment would be levied, some disgruntled stockholder would forthwith tell the Commissioner that the assessment was not necessary, and that official would have to go to work, examine the books and papers, examine the mine itself, and make a report; all of which couldn't be done in ten minutes, or ten days for that matter, if done properly.

When we consider the scope of country over which a man might have to travel to visit the various mines which are incorporated and which would be liable to come under his supervision, it becomes evident that a single Mining Commissioner could not attend to his duties. If the business were done by deputy, little reliance could be placed on the report. In fact,

it would be difficult to find any one man to place in so responsible a position, as the office would soon become a political one and be filled by politician, who, after the manner of the class generally, would immediately proceed to fill his pockets.

Under the plan offered by the Dispatch this commissioner would have as fine an opportunity to amass a fortune, in a few years, as any official in the world. The position would be a veritable bonanza to the occupant, and be as valuable as the best mine on the coast, not excepting the Consolidated Virginia. The commissioner would be a perfect autocrat, and would have the authority to say which mine was valuable and which worthless. Any one can see that the chances for irregular practices would be many and tempting. Where the value of one man's opinion was worth \$50,000 to make a mine worth \$500,000, the \$50,000 would be forthcoming, no doubt. A mining engineer would be very well to examine the mines themselves, but few of them would make any pretensions of knowledge of the business details of corporations.

We are afraid that the plan would not do. Even half a dozen or dozen commissioners could not do the work if done properly. Moreover, the people have, within the past few years, come to look upon officials as money grabbers and little else, and would have small confidence in any man who would have such chances for personal aggrandisement. It is a deplorable fact that there are dishonest companies, but legislation to prevent people making fools of themselves, or taking care of their money for them, has never been successful. If, after any doubtful transaction is found out about any man who is a director or trustee of any incorporation, the people would steadfastly refuse to have the slightest thing to do with anything in which he was interested, the evil would be gradually overcome. It would bring a better class of men to the front, and those whose acts shun the light of day would have to retire to darkness themselves. But we must confess that we do not think that the appointment of a mining commissioner would remedy the evil. It would only create one more officeholder, and would make no more honest companies than there are now.

Direct Undercurrent for Hydraulic Mines.

Lorenzo D. Stephens, of Gold Run, has recently obtained a patent through the agency connected with this office, for certain improvements in the sluices which are used for separating and amalgamating the precious metals in hydraulic mining. The invention consists mainly in the construction of a direct undercurrent, whereby the amalgam which may be formed in the long period of time which elapses between cleanings up is protected from depredation, by means of the constant and large quantity of water and rocks which are perpetually passing over the chamber within which it is contained.

The sluice is made in the usual manner with blocks of wood set on end for a bottom. At intervals along the sluice are openings, in which iron bars are placed, which extend across the sluice. Beneath these bars is a space which extends a short distance across the sluice and is covered over, after passing the grating, by an iron plate. Within this space riffles are placed along its bottom, and these riffles are filled with mercury. At the lower end of these riffles, and upon the same general plane, the blocks which form the next section of the sluice commence, so that there will be an offset from the plate over the space, and the plane of the upper section, to this lower plane, wherever one of the riffles occurs.

The iron plate is employed where there is a very limited "drop off" or fall, but where the grade will permit, the inventor substitutes for the iron plate planks placed crosswise in the sluice and forming a false bottom, sufficiently elevated above the riffles to leave space for all the fine particles to pass through. This false bottom will be as low as the bottom of the blocks, and upon it is placed another series of wooden blocks, the tops of which are on a level with the grate bars. These blocks extend to the lower end of the riffles, and have a fall at this point upon the next series of blocks lower down the flume, in the same manner as when an iron plate is used. The blocks wear less and are more economical than iron, where they can be used.

The operation of this sluice is as follows: Water and the auriferous earth are turned into the sluice. The rocks and coarser gravel will pass over the grating, and fall from one level to another, passing down the sluice. The finer sand, gold and some mercury with some water, will pass through the grating and be carried over the riffles, the mercury and gold being stopped in these riffles, while the sand and water will flow out upon the next section below; and this process is continuous throughout the sluice. This direct undercurrent being in the line with the flume or sluice cannot be interfered with by outside parties, as the amount of water, gravel and large rocks passing would imperil the life of any would-be robber.

A two and a half foot vein of pay ore has just been struck in the Hussey mine at Coronopia, eighteen inches of which average \$334 to the ton, the rest being of low grade.

A California Bonanza.

We have examined this week some of the richest gold ores we have ever seen in any quantity. A few hundred pounds of it were sent down from Carson Hill, Calaveras county, California. This ore has just been taken out of the old Carson Hill-Melones property, which mines were worked a number of years ago, but were eventually abandoned, and no work done for some eight or ten years. About two months since work was again resumed by the Melones Consolidated mining company, which includes all the old claim on the hill. This ore is from the old works of the Stanislaus mine, near the river and 100 feet from the surface. The ore was taken from a strigger in the fifteen foot ledge a short distance from the side of the shaft. The feeders are immensely rich in tellurides of gold and silver. This ore which we saw is thickly studded with massive gold, standing out from it in great rough lumps that would brighten the eyes of any old miner. We are afraid to say how many thousand dollars or two the rock would go, but it is so rich it is not to be milled but smelted out.

These mines have been closed down since 1865 for various reasons, among them the difficulty of working the tellurides and want of working capital and reduction works. Mr. G. K. Stevenot, the principal owner, spent a fortune in expensive litigation, but has always had confidence in the property. The mines were pretty thoroughly opened by tunnels and shafts and two mills were put up, but although most magnificent assays were made little was produced from most of the ore, no one understanding how to work it. Lots of it assayed from \$3,000 to \$5,000 per ton, but only five per cent. was obtained by mill process. The difficulties of working the ore have been overcome and Mr. Stevenot is doubtless now about to reap the reward of his perseverance.

The famous Morgan mine, which produced \$1,500,000 in 1850-51 by arrastras and hand mortars, is on this property. The Stanislaus lode, which produced the rock of which we speak, has rich deposits in chimneys and small quartz feeders, which follow the line of slate formation. The compact quartz vein varies in thickness from four to fifteen feet. The free gold on the surface was soon replaced by tellurides and sulphurets, and although various difficulties caused the closing down of the mine those who were familiar with it—Jas. G. Fair, of the Consolidated Virginia mine, among the number—were sure that it would eventually be found to be a very rich mine. Mr. Stevenot has been endeavoring for years to get some one to take hold of the thing with him, but with poor success; but he says that when his rich rock came down the other day he had offers from several for unlimited capital. Now, however, he can stand alone and don't want any capital but thinks he can prove that California gold mines are as good as Nevada silver mines. We are pleased to mention this strike in the old works of this abandoned mine, especially in so short a time after work has been resumed, and note it as a feature of encouragement for others in similar positions. We hope within the next few years to see hundreds of old mines re-opened and active operations commenced upon them. Mines that would not pay ten years since will pay now, and every one has the chance of striking a "bonanza" in any claim they may take hold of.

The snow plows in use on the Central Pacific railroad are a curiosity both in their construction and in the manner in which they do their work. They are immense structures, almost as big as a two-story house and weigh from 45,000 to 55,000 pounds. In front they are shaped like the iron prow of an ironclad frigate, only the sharp vertical portion of this prow changes to a flat surface where it approaches the ground. Attached to this flat or horizontal prow is what is called an "apron." This apron is attached to the prow by means of hinges. It lifts up and lets down directly on the track at pleasure, and when down it is held there by large steel springs. When in motion this apron slides right on the rails, pressing hard on them; but from the rounded surface which it presents to them it glides over the joints and any other little irregularities with ease. The long prow is pushed under the snow, the apron scraping it clear from the rails, and, lifting it up bodily, it meets the vertical section of the prow, which divides it and hurls it off on either side. When running at a high rate of speed, as is often the case, these plows sometimes hurl the snow into the air fifty feet and plunge it in huge masses into the deep chasms and canyons.

THE SUTRO TUNNEL is now in from the mouth to face of header 12,037 feet. The main header, of course, as everybody understands, is a large sized prospecting drift, running in advance of the main tunnel. During the past week a strong force of hands has been put to work enlarging it to the full size of the tunnel, between the air shaft and shaft No. 2.

THE NEVADA CITY powder works will soon be in operation, and expect to produce powder at a cost far below that at present paid in the State. A fruit drying establishment is also projected in the same town.

THE OSWEGO iron works, Oregon, turn out 1,000 tons of pig iron per year, most of which is exported to San Francisco.

Hydraulic Gold Mining in California.

[No. 7.—Written for the Press by C. J. Brown.]

As announced in my last I now proceed to give an account of the preparations for hydraulic mining on the "Polar Star" and "Southern Cross" claims. As before stated, both are under the charge of one man—Mr. Colgrove—and, in part, work jointly. The South Yuba company's ditch, from which these two companies take water, runs along on the mountain side, to the south of the railroad, high above these claims. Mr. C. takes water from the ditch by means of a flume laid at right angles with the ditch, twenty-four feet long and of large capacity, which conducts it in the measuring box or boxes (for all this work is double), 18x21 feet. The water is measured through a four inch aperture along the whole extent of the front and both sides of this box. In front of the box and attached thereto is a four-foot flume, sloping with a slight grade from the center, where there is a division, both to the right and left. On each side of the box is a similar flume with a similar grade, which extends forty feet below the front of the measuring box to the double sand box. This sand box is 12x24 feet, 9 feet high, with a division in the center, which makes two boxes twelve feet square. Each of these boxes has a partition five feet high running from the front to the rear through the center, so that the floor of each is divided into two compartments 12x6 feet. The water drops into the outside compartment of each box, provided respectively with sand gates at the bottom and waste gates at the top. Of course the water must rise above the five-foot partitions before it can flow into the inner compartments next to the main center division.

The twenty-four foot flume is provided with a screen set at an angle of about thirty-five degrees. It is common among miners to set their screens perpendicular, but it is much better to set them up as low an angle as possible, that the debris collected may crowd up on to them above the level of the water. Each sand box is also provided with a screen which slopes from the top of the five-foot divisions to the top of the main center division. The whole is securely covered, and a trap door, under lock and key, provided for each main compartment as a precaution against any damage to the pipes from the insertion of large or heavy substances by evil disposed or careless persons. Over twelve thousand feet of the best quality of lumber has been used in the construction of this preliminary work. There is, perhaps, nothing very new or novel about this whole arrangement, certainly not to the miners of this section. One of Mr. C.'s main objects, however, has been to provide securely against the constant flow of air bubbles into his pipes. This has been a great source of annoyance, damage and loss to hydraulic miners, and many devices have been tried to remedy the evil.

Allow me to digress a moment while I call attention to the discussion of this subject by a certain writer, as published in "Mineral Resources West of the Rocky Mountains," for the year A. D. 1873. Under the caption of "Iron Pipes," (see page 410), he writes elaborately of one or two "simple arrangements" which he thinks "would secure the undisturbed flow of water and permit the air to escape as it accumulates, without interfering with the water rushing into the pipe." Again, he uses this expression: "The air which necessarily enters the feeding pipe with the rush of water," etc.

Why "rush" water into a pipe, especially water containing air bubbles? Air does not "necessarily" enter the pipe with the water. Of course, he is writing not only of the air which for a few moments will disturb a stream issuing from a pipe upon first being filled, but more particularly of the continuous disturbance of a stream by the constant flow of air bubbles through the pipe while in use, for he gives us to understand that "the advantage to be gained from this arrangement," (recommended by him for hydraulic pipes), "would be the almost total exclusion of air from the feed-pipe, and, therefore, the certainty of a solid and even discharge of the water from the hydraulic machine, securing the greatest efficiency and force of the water jet."

My! This gentleman, about the year of our Lord, 1873, must have awakened from a long Rip Van Winkle sleep, for the very devices which he describes and recommends as pipe attachments, as well as more simple and effective ones, had been thoroughly tried and permanently discarded by the miners hereabouts long before his article was published. (I make no reference to air valves along the body of the pipe, which are still in general use.) Except when the pipe is first filled, all the trouble from air has been caused by "rushing" water containing air bubbles directly into the mouth of the pipe. It is well known that the slightest fall of a stream openly exposed to the atmosphere—as water dropping into a sand-box—will force air down into the water beneath. It is also well known that, in what the miners call "dead water," the air so forced down will quickly rise to the surface and again join its natural element. Why, then, not allow it to escape through dead water before reaching, instead of rushing it into the head of a hydraulic pipe?

Instead of entering at the side, as is usual, the pipes for these two claims enter the sand box, near together, on either side of the main center partition, up through the bottom; so

that, when the boxes are full, there will be a solid body of almost still water over the head of each pipe, eight or nine feet deep, and about the same distance to the side of the streams entering the boxes, with the five-foot partitions intervening. When once filled it will be very difficult for air to enter either pipe with a "rush" of water.

These Pipes

Are constructed from Nos. 14 and 16 sheet iron, and are each four feet in diameter at the head; they taper gradually for 500 feet to the size of twenty-two inches; with this dimension they extend 2,800 feet to a twin (so called) provided for each; thence two fifteen-inch pipes extend to either claim, about 500 feet. Each pipe gives a pressure of 500 feet, and has a capacity of 2,000 inches of water.

The pipe will all be painted with red lead, that being the only substance, yet tried, which prevents the pipe from corroding. Each claim will have two of Hoskin's giants, and when once fairly opened will have as fine rigging, and, I predict, will pay as well as any hydraulic claims in the State, for the ground is known to be rich.

Shaft or Incline?

The opening of these two claims is likely to settle a long mooted question among the miners of this district, as to which is preferable—a shaft or an incline; neither lacks its advocates, and both have been tried in working off the top bench of gravel. The incline is given the preference in opening through comparatively light gravel. The Yankee is the only claim which has worked the heavy bottom stratum. It works through a shaft, and Col. Ludlum, who champions the shaft, is now sinking another on his line of works, while Mr. Colgrove has raised an incline on the Polar Star, and purposes to do the same on the Southern Cross. Not being a practical miner, I feel a little timid

they have been introduced, and there will probably be a large demand for them the coming season, if our present prospect of good crops holds out. Farmers and threshers visiting the city are invited to call on this firm and examine the engines on exhibition at their store. The illustration on this page, for its size, gives a good idea of the engine, showing the man in the act of getting up steam with straw. The engines are eighteen horse-power, and fitted with the Shive governor.

Many of our farmers who live in places where wood is plenty have not yet seen the straw burning engines working, and some of them even refuse to believe it possible to keep steam with straw to run a threshing machine steadily. Firing with straw is not difficult. I took a boy who had never fired an engine and put him to feeding straw. He watched me firing for about ten minutes and then I let him go to work, showing him a little about keeping the fire right. I had plenty of steam the first day.

As far back as the year 1856 a mill of six pairs of stones was successfully driven by a straw burning engine. This mill was situated on the Pardang estate, in Lower Hungary, and since then the established fact of the possibility of straw being used for the generation of steam has led to a dozen, more or less, good patents being taken out in England, some of which are now working successfully in Hungary and other grain growing countries.

There are over 200 straw burning engines in Hungary. Over fifty of these are made by Garrett & Son, an English firm. They all use the ordinary fire-box boiler, but made somewhat larger than for wood and coal. The makers of straw burners in this State say they cannot burn straw in fire-box boilers, and have all adopted Mr. Rice's plan of the return-tube boilers, generally known as the Cornish boiler. Messrs. Fowler, of Leeds, England, have

altered a coal burning engine for the season of 1875, and did considerable of the work myself. It then cost me about \$900. The engine worked well. The boiler made plenty of steam with ease. I threshed three months with this engine in San Joaquin county and at Halt Moon bay, and will say that I consider straw the best fuel, preferable to wood or coal, even if the cost of straw was equal to that of wood or coal.

An even pressure of steam can be kept easier with straw than with wood or coal. The straw must be fed steadily. If overfed the main fire is filled up, much smoke is made and the fire smothered. The effect of feeding straw too fast is about the same as feeding too slow. In one case the fire is smothered and in the other the engine draws too much cold air. In either case the steam pressure is reduced.

There is less danger of fire in the field from straw burners than from wood, which fuel is generally used in this State. There is no need of pulling the fire out when going to the next stack, as is often necessary when burning wood. A fire occurred from this cause near where I was threshing, in the season of 1874. An engineer pulled his fire just before moving in the evening, and threw some water on the burning wood, but did not put it out. A few hours after, and in the night, the stubble caught fire from this wood, and the fire ran to the next stacks, where the machine had moved to, also to another machine near by; both separators, driving belts, tools, four stacks of wheat and a lot of empty sacks at each machine were destroyed by this fire.

The farmers prefer the straw burning engine. Threshers who have straw burners do not have to look for work—the work looks for them.

J. W. RILEY.

Hardware.

The great depression that pervaded the business community during the past year has been shared in to its fullest extent by that branch of trade now under consideration. The close and increasing competition and the heavy expense of conducting the business has rendered the strictest attention to details necessary, and the time is fast approaching when dabblers and speculators will have to withdraw from the market, leaving the business in the hands of the practical few who have made it the business of their lives. When this normal condition of affairs is reached we may expect it to be a profitable pursuit, and not before. Another existing evil of the trade is the want of a proper classification. Nails, rope, iron and steel, and agricultural implements are now handled almost exclusively by the hardware dealers, whereas they are each separate and distinct branches of themselves, and should be so conducted. Nails and rope have been the bane of the business for many years and will continue to be until they are dropped from the lists.

Among the recent changes in the trade, the most important has been the purchase, by Jas. E. Gordon, of the stock and business of Pillsbury, Hussey, Adair & Co., formerly Marsh, Pillsbury & Co. Mr. Gordon is well known in the community, having been a resident since 1849, and brings to his aid a practical experience of fifteen years in the business in this city. The ranks of the trade have also been increased by the advent of Frank Bros. & Co., whose specialty will be agricultural implements, and having large means at their command, will do a very extensive business in the line. The market has been free during the year from the violent fluctuations in prices in the East which has marked former years, neither has the premium on gold varied sufficiently to be worthy of note, although the variation was greater than for the preceding year. These elements of stability have been of material service to the trade in preventing any more serious results from the financial panic precipitated upon us by the failure of the Bank of California and its attendant evils, from which we have not yet fully recovered.

While prices in 1875 did not fluctuate to any great extent, there was a steady, gradual decline throughout the year, there having been no article of any importance on which we can report a marked advance during the same period. Nails which at the opening of the year were selling at \$4.25 rates are now jobbing at \$3.75 rates. A strong effort to introduce the product of the Western mills has been rewarded with fair success, although the Eastern nail still holds the market. In this connection we note a growing demand for the Anchor brand, made in Baltimore. Bar iron has declined a quarter cent per pound, but has ruled very steady, considering the low price in the East. Shovels and spades, and other steel goods have declined materially, as have also brass and iron screws; with the latter we expect to drive out the English article. American files and saws have made the once favorite English brands almost unknown, while Pittsburgh steel has given the English article a severe set back during the year. Among the varied articles that go to make up a hardware stock, there is one that generally receives but little attention, and yet is of the utmost importance to a large majority of our manufacturers, and that is the item of sand paper. A great void has hitherto existed in this particular, which has just been filled by the introduction among the trade of "New England flint paper," an article of rare excellence in its way. The trade in builders' hardware and mechanics' tools was lively during the past year, with excellent prospects for 1876.

STRAW-BURNING ENGINE.

about advancing my own opinion as to the merits or demerits of either; but I confess that my frequent observation of the hydraulizing in the Yankee, and what I conceive would be the result of attempting to work off such masses of heavy boulders through an incline—inclines my head to the shaft; nevertheless, "chewing the string is proof of the pudding," and I await further developments, hoping that both plans are best for those who adopt the one or the other, according to the quality of gravel to be washed.

Dutch Flat, January 28th, 1876.

Straw Burning Engines.

Straw burning engines for steam plowing and threshing are considered the latest improvement in agricultural machinery by our valley farmers, who have had an opportunity to see them working successfully. There were about forty of these engines at work in the State during the harvest of 1875. Mr. H. W. Rice, of Haywoods, made over one-half of this number. But for his experience and experiments, in connection with Mr. D. Morey, of Watsonville, our farmers would probably not have had a straw burning engine at work in this State yet. Mr. Morey obtained a patent in 1873, and a re-issue in May, 1875; Mr. Rice obtained a patent January, 1874, and re-issue in May, 1875. Credit is due Mr. Morey for his persevering efforts to obtain a suitable feeder for this style of engine. This system of feeding straw is very simple and effectual, as it excludes all cold air from entering the boiler above the fire, which it is impossible to do with the ordinary furnace with wood and coal. Messrs. Rice and Morey have sold their interest and right to make these engines on this coast to Marcus C. Hawley & Co., Nos. 108 and 110 Front street, San Francisco, and corner of Second and J streets, Sacramento. They are making arrangements to manufacture a large number of the Rice straw burning engines for the season of 1876, as every engine manufactured last year found a ready sale, although the crops were light. They are a favorite engine where

constructed two 12-horse (English nominal) traction engines for use in Russia, which are to be fired with straw (fire-box boilers). The engines are intended for steam plowing, and this work is much heavier than threshing. These engines will have to indicate 60-horse power. Under these circumstances Messrs. Fowler did not like to rely on straw alone, so a tank is provided, standing across the top of the boiler, and from this petroleum can be blown in spray into the fire-box. Some trials of the engines have been made which, even with English straw of inferior quality, gave eminently satisfactory results, and there is no reason to doubt that with straw of Russian growth the results will be quite satisfactory.

Messrs. Ransome, Sims & Head, of Ipswich, England, sent one of their patent straw burning engines to this city last spring. This engine has an ordinary fire-box boiler, made larger than a coal fire-box. The straw is put in by means of a pair of toothed rollers. The rollers are run by a belt from the engine shaft, at a speed of from forty to fifty revolutions per minute. This keeps a small but steady supply of straw going into the fire all the time. By special invitation of Messrs. Ransome's agent, in this city, I attended a private trial of this engine at his place some months ago. The engine worked well, consuming the straw thoroughly. The straw, of course, makes some clinker, which is readily removed by an arrangement of bars between the grates, moving to and fro easily and quickly, clearing the fire. This engine will probably be used during the harvest of 1876, and the readers of the RURAL who are interested in this subject may look for a more detailed account of the work of this engine.

As this or some other arrangement is much needed in our State, an attachment that can be applied to the many engines now in use for the successful burning of straw would save our farmers many thousand dollars. Unless we have an attachment for this purpose that will work successfully, second hand wood and coal burning portable engines will become a drug in the market. To remove the old engines from the boilers, and purchase a new boiler of the Cornish style, put the engine on and remount it, will cost from \$1,000 to \$1,300. I

[PUBLISHERS' ANNOUNCEMENT.]

MINING AND SCIENTIFIC PRESS

For 1876.

THIS PUBLICATION, SO VALUABLE FOR
MINERS, MECHANICS AND
MANUFACTURERS,

Will enter upon its THIRTY SECOND Semi-Annual Volume on Saturday, January 1st, 1876. It has ever been and will still continue to be the aim and object of the publishers to make the Press

A Practical and Interesting Journal.

To this end, we aim, through the constant watchfulness of our editors and correspondents, to seize upon everything new in the way of mining and the various processes connected with the saving and separating of the precious metals, and place the same before our readers at the earliest day. It has been well said that

A Newspaper is a Window

Through which men look out upon all that is going on in the world. Our window is a special one, so placed and arranged as to bring within the scope of its vision all that is going on

In the World of Mining, Mechanics and Science.

Without a paper of this kind, this miner or mechanic is shut up in a small room or shop and can know but little of what is going on in the world around him in relation to his particular calling. In this age of rapid progress books are necessarily slow and behind the times. It is only through papers devoted to the specialty which he has chosen that one can be easily apprised of the discoveries and improvements which are constantly being made by his fellow workers, and without a knowledge of which he soon becomes a lag-gard in the race.

The Value to the Community

Of such publications in disseminating important information, in checking needless and exploded experiments and in instigating important enterprises, can scarcely be overrated. Through them the readings and observations of thousands are collected and collated, and brought directly to the shop or table of the reader, without any effort of his own. For a mere trifle of cost he is regularly furnished with an encyclopedia of just the information he needs—an unbound book forever issuing but never finished.

Nowhere in the Wide World

Is such an aid more needed than by the miner of California. It is needed alike in the mill, in the mine and in the placer. We have here

The Largest Mining Field on the Globe,
Embracing a variety of minerals nowhere else found within the boundaries of a single field. We have here also, men gathered from every quarter of the globe bringing with them the collective wisdom of the world,

Useful, Practical and Directly from the Field

Of labor. The mustiness of books has been brushed away, and their minds are stored not only with the experience of the past, but also with the practice of the present. It is to this fact that we are indebted for our present

Able List of Correspondents,

Through whom we are able to promise to our readers so much that cannot be collected in the mere routine of office work. By the aid of such help our editors will be able, during the coming year, to do more than ever in furnishing information which shall be

Fresh, Novel and Interesting,

And which shall comprise all that is known of the latest and best means for saving gold and silver, and for economizing labor and cost in that direction.

Our Illustration Department

Will still continue to form an important feature, and no effort will be spared to make it of the greatest possible local and general interest to our readers. The important matter of

Home Manufactures and Inventions

Will also largely occupy the attention of the publishers and editors, and will be constantly encouraged, as an important means of furnishing employment to those who are seeking our shores, and adding to the wealth of the Pacific coast.

The Large and Increasing Circulation
Of a journal thus devoted exclusively to useful and practical information, speaks more in our behalf than anything we could say of ourselves, and is an encouragement to its further increase, especially in these times of trading and trashy journalism.

The class of readers who are interested in such a publication as this, have no need to be anything more than merely reminded that such journals are necessarily more costly than those of a lighter class, such as are read by the "million" and thrown aside as soon as read. Considering the character and location of the MINING AND SCIENTIFIC PRESS, our rates are as favorable as can possibly be afforded and do justice to the great industries in aid of which we are laboring.

A Handy Map

Of California and the principal portion of Nevada will be furnished free to all subscribers who pay one year in advance, during the year 1876. The map is plain, printed on tinted paper, about 16x20 inches, showing townships in California, and the counties, railroads and principal towns in California and Nevada.

We Prepay the Postage

On all papers sent to subscribers in the United States. SUBSCRIPTION RATES, payable in advance: One year, \$4. Sample copies free to those who will assist in obtaining subscribers.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.
It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.
In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produce a finish superior to any other White known.

Put up in $\frac{1}{2}$, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.
For further information send for Sample Card and Price List, or apply to the office.

OFFICE AND DEPOT: FACTORY:
117 Pine Street, near Front. Cor. 4th & Townsend Sts.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets & Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.
DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a wash tub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward.

For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical purpose, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.

FOR SALE BY ALL THE LEADING JOBBERS.

Geo. M. Grant & Co., Agents. San Francisco.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-Inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 3-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

Address, FRASER, CHALMERS & CO., Chicago, Ill.

Buffalo Excelsior Pony Planer & Matcher.

Patented March 30, 1875.

Best of its kind in use. Price, complete, \$75. Also, small Pony Planers and Planing Machines, Knives, which are recommended as superior and extra in quality. 100 Scroll work designs free on receipt of stamp. For circulars giving detailed information, address GEO. PARK, Buffalo, N. Y.

Excelsior

LATEST IMPROVEMENT.

Scroll Saw.

Saw only without attachments, \$9.

Double Treadle, including one doz. Saws, thirty immitable Fret Sawing Patterns and Prepared Wood to the value of \$4. A new device for tightening Saw, Power Drilling attachment, Wrench, Oil Cup and Driver, Speed, 800 strokes per minute. Saws 1 1/2 in. thick. Price, complete, cased and delivered on board cars or at Express office, \$12

GEO. PARK, Buffalo, N. Y.

BUFFALO PONY PLANER.

Nearly One Thousand in Use.

BUFFALO PONY PLANER Will earn itself and pay expenses of running in 8 days. Price from \$60 upwards, each. Also, small Pony Planers and Matchers, and Planing Machine Knives. Recommended as superior and extra in quality. Circulars free. One hundred Scroll designs free on receipt of stamp. Address GEO. PARK, Buffalo, N. Y.

DUNHAM, GARRIGAN & CO., San Francisco, are Sole Agents in California for any Heavy Wood Working Machinery.

Little Giant
IMPROVED LEVER & CRANK
ATTACHMENTF. HOSKIN,
Dutch Flat, Cal.,
MANUFACTURER.

This Machine is perfect in its operation, and is guaranteed to give satisfaction.

SANBORN & BYRNES,

Mechanics' Mills, Mission Street.

Best First and Fremont, San Francisco. Orders from the country promptly attended to. All kinds of Stair Material furnished to order. Wood and Ivory Turners, Billiard Balls and Ten Pins, Fancy Newsels and Balusters. 25 1/2-8m-lip

F. MANSELL & CO.,
SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Gents' Furnish'g G'ds.
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,
	Wine Merchants, Etc., Etc.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.

By Special Dispatch, Dated Washington D. C., Feb. 1st, 1876.

FOR WEEK ENDING JANUARY 18TH, 1876.*

ORE FURNACE.—Horatio G. Livermore, S. F., Cal.

WATER HEATING ATTACHMENT FOR STOVES AND RANGES.—James H. Mitchell, S. F., Cal.

COLOR PRINTING BLOCKS.—Joseph Perkins, S. F., Cal.

MACHINE FOR TREATING RAWHIDES.—Herman Royer, S. F., Cal.

Coupling for Train Telegraphs.—Andrew Ryder, Oakland, Cal.

FRUIT DRIERS.—George A. Deitz, Chico, Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

ORE ROASTING FURNACES.—Horatio G. Livermore, S. F. Mr. Livermore has two distinct patents in furnaces. The first is an improvement in furnaces for roasting or desulphurizing fine ores, which consists in a novel construction of a furnace having a floor placed at such an angle that the ore, if left to itself, would slide to the bottom. The space between this floor and the top is comparatively limited, and is crossed by numerous dams or abutments, so that the ore will be detained and will only move when a portion is withdrawn from below, when the whole body of ore will move downward, the dams serving to stir and turn the ore and loosen it so that the vapors can escape and a new surface will be exposed to the heat. The furnace is situated at the foot of the incline and the heat passes up over the body of ore and is deflected upon it. Suitable feeding and stirring devices and passages for the escape of fumes to the condensers are made. The body of ore being so thin and so thoroughly exposed to the heat will be roasted almost as fast as it can be fed and withdrawn at the bottom, the operation being continuous.

The second patent is for a furnace more particularly adapted for quicksilver ores. It consists in the employment of two or more fireplaces upon the sides of the ore chamber, so placed that the heat will have its fullest effect upon the ore, while at the same time the ore will be prevented from passing into or clogging the fire flues, without the necessity of arches or fenders of any kind. Above the fireplaces are passages which branch out from the ore stack or chimney and open into a chamber which extends entirely around the ore chamber and collects the vapors from it in readiness to deliver them to the condensers. By this construction the inventor is able to provide a continuous working furnace in which the greatest heat passes through the ore while it is contained in a narrow place, the heat passages are not clogged and a free escape is provided for the fumes.

WATER HEATING ATTACHMENT FOR STOVES AND RANGES.—James H. Mitchell, San Francisco. The object of this invention is to provide an improved water heating attachment for stoves and ranges, to be used instead of the copper boiler or reservoir ordinarily employed for that purpose. It is well known that the copper boilers at present in general use for supplying hot water in houses are liable at times to interfere with the cooking operations of the stove or range, owing to the abstraction of heat therefrom by the rushing in of a quantity of cold water to supply a vacancy caused by drawing off water from the boiler; thus often lowering the temperature when it is necessary to maintain a uniform or high degree of heat for cooking. There are also many other disadvantages connected with the use of these boilers, such as their liability to leak, collapse, burst from freezing, etc. Mr. Mitchell's arrangement is to overcome these difficulties and supply hot water to houses by a better method. He is a man of experience in this line and the invention is not by any means an experiment.

Instead of surrounding the stove or range with a water jacket for supplying hot water to a boiler located above it, he places the hot water tank or reservoir in the upper story or attic of the building, or on the roof, if found most convenient. This tank can be made of wood or metal, and its upper end be left open like any ordinary tank. A water pipe leads from the mains in the street, and an ordinary cock operated by a float serves to keep the tank filled. A pipe is then led from near the bottom of the tank through the wall of the chimney, and thence down along the wall in-

side of the chimney to a point opposite the stove. It then passes through the wall of the chimney and into the stove or range, where it is boiled in the fire chamber, and is thence led back through the wall of the chimney, thence up along the inside of the wall, where it again passes through the wall and into the tank near its top.

This pipe, it will be readily perceived, is a circulating pipe, by means of which the water in the tank can be heated to the boiling point. As the water in the coil which is inside of the fire-place becomes heated it rises in the pipe, giving place to the colder water, and thus a circulation is established and maintained until all of the water in the tank is heated to a uniform temperature. Branch pipes can be led off from the circulating pipe to any part of the house, so as to supply water in every room if desired, and suitable pipes can be applied between the stove and chimney, by means of which hot water can be drawn in the kitchen and which will serve when desired as a means of cleaning out the pipes and tank. When hot water is drawn off from the pipes the cold water which takes its place in the tank will be raised to a considerable temperature before it reaches the range, so that it cannot much affect the heat of the range. While the inventor thus does away with the copper boiler he provides for supplying a double quantity of water in a more convenient manner throughout the house, and as the circulating pipes pass up close against the heated wall inside of the chimney, the loss by radiation is diminished at least fifty per cent., while in cold weather the wall of the chimney will retain sufficient heat through the night to keep the water in circulation and prevent its freezing. By this arrangement the inventor is able to supply a much larger quantity of hot water and more direct to any part of the house, and at the same time avoid the use of lead pipes, the oxidation of which is known to be poisonous. Any kind of stove or range can be employed in this circular with much less heating surface in the fire chamber, thereby saving a large percentage of fuel. The pipes can be readily detached from the stove or range, without the aid of a plumber, by simply turning off the water at the stops between the chimney and stove range and disconnecting the coupling which connects them.

COLOR PRINTING.—Joseph Perkins, S. F. This invention relates to improvements in color printing, which are more especially applicable to printing oil cloths where many colors in a thick medium and small and intricate patterns are employed, and in which the printing has hitherto been done by many impressions. The improvement consists in the employment of a pattern block having two or more tubes or passages leading to its face, so that as many colors may be applied at one time as may be desired. It also consists in the employment of a system of reservoirs for each of the tubes and converging connecting tubes opening into them, and a means for producing a pressure upon the surface of the point in the reservoirs, so that a supply of colors is continuously led to a printing surface within a narrow compass, so as to form a colored pattern. The invention thus overcomes the difficulty hitherto met in this class of color printing that the thick medium employed and the smallness of the patterns has necessitated numerous impressions and the use of a single color at each impression.

TIRE UPSITTER AND PUNCH.—John H. Mertz, Paso Robles, San Luis Obispo county. This is an improvement in that class of machines which are employed to upset or shorten bars of iron and more particularly wheel tires, and in a combination with the same a punch for perforating metal plates or bars.

In the Overman mine the connection has been completed between the west drift of the 1100-ft level and the bottom of winze from the level above, giving a much needed ventilation of the level, and furnishing a good supply of pure air. A cross-cut has now been started to cut the ledge and determine its value. The result is looked forward to with a great amount of interest, and is in reality a feature of more than ordinary consideration to all the mines on the south end of the Comstock.

R. W. RAYMOND, United States commissioner on mining statistics, having engaged Frank F. Osbiston to furnish him a report on the mines of the Comstock range, the latter has delegated S. V. Mooney to visit the superintendents of mines in that vicinity for the purpose of collecting the data required for the intended report.

Trouble is brewing between the Woodville and Rough and Ready mines, the proprietors of the latter having sunk a shaft directly between the old and new shafts of the former. The Woodville folks have warned them off, but they keep on working, and a lawsuit is probably the next thing in order.

The new Consolidated Virginia assay and bullion reduction works are fast approaching completion, and when done will without doubt be not only the largest but the most complete in all its appointments of any private assay office in the world.

On the Julia mine sinking the shaft and driving the drifts on the 1600 and 1500-foot levels is prosecuted at all points with burleigh drills, and is making as good progress as is being done in any mine on the Comstock lode.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

OLIVER M. Co.—Jan. 28th. Object: To mine and carry on the business of milling in California. Directors—A. K. Grim, Wm. H. Bruner, John F. Cooper, S. H. Cowles and Allen Oliver. Capital stock, \$2,340,000.

METALLIC M. Co.—Location: Columbus mining district, Esmeralda, Nev. Directors—George S. Dodge, T. B. Shannon, S. Reinhardt, A. B. Townsend and Jeremiah Maynard. Capital stock, \$5,000,000.

UNION PLAC M. Co.—Feb. 1st. Location: Gold Hill, Nev. Directors—Gustavus Cox, G. J. Fray, A. H. Yeazell, Henry Bredhoff and Frank L. Sullivan. Capital stock, \$10,000,000.

TENNESSEE HILL HYDRAULIC GRAVEL M. Co.—Feb. 1st. Location: El Dorado Co., Cal. Directors—Herman Levinson, Maurice Dore, Alexander Ansdin, George F. Maynard and Henry Marshall. Capital stock, \$5,000,000.

CRATER G. M. Co.—Feb. 1st. Object: To carry on a general business of milling and mining. Directors—A. Fray, J. W. Whitlatch, O. D. Morrison, J. A. Wells and N. O. Fasset. Capital stock, \$6,000,000 in 60,000 shares.

NORTH LEOPARD M. Co.—Feb. 2d. Location: Cornucopia district, Nevada. Directors—George Hest, C. R. Great-house, Chas. S. Drew and Theodore A. Brown. Capital stock, \$10,000,000.

THE CALIFORNIA CONS. M. & M. Co. has filed a certificate of increase of capital stock from \$3,000,000 to \$6,000,000.

THE SOUTH JUSTICE M. Co. has filed a certificate of increase of capital stock from \$5,000,000 to \$10,000,000.

Meetings and Elections.

WELLS-FARRO MINING Co.—Jan. 28th. Trustees: D. L. McDonald, H. Z. Wheeler, G. W. Hammer, A. O. Taylor and R. F. Bunker. The income of the company was \$49,362.15, mainly from assessments 1, 2 and 3; and disbursements amounted to \$48,354.11.

BIO TREE CONSOLIDATED G. & S. M. Co.—Jan. 28th. Calaveras county, Cal. A. K. Grim (President), J. Baker, Jr., N. B. Stone, Wm. Murphy, W. A. Keele, Trustees; and O. A. Sankey, Secretary.

EUNOPA.—S. K. Thornton has been chosen trustee of the Europa, vice H. O. Kibbe, and C. L. Weller selected Vice President.

FLORIDA M. Co.—Feb. 2d. Trustees: E. W. Leonard (President), O. Eldredge, J. Halladay, Wm. Fraeuvorn and Josiah Belden, Trustees. L. Hermann, Secretary, and P. G. De Noon, Superintendent.

NORTH CONSOLIDATED VIRGINIA.—Feb. 2d. Trustees: R. O. Rogers (President), H. P. Waklele (Vice President), E. M. Fry, N. B. Stone and Geo. W. Hopkins; Secretary, Joseph Maguire; Superintendent, D. H. Jackson.

The Belcher company have elected John Crockett Secretary in place of the late Secretary, H. O. Kibbe.

The pumping machinery in the Utah mine is finished, after a few tests it will be set regularly to work to drain the water from the shaft, and as soon as that is exhausted, and any damage that may have happened to the shaft is repaired, work on the lower levels will be resumed.

THE WAGONTOWN mines in Idaho are reported as turning out splendidly. New arrivals are noted every day, house rents are very high, a small house bringing from \$75 to \$100 a month, and it is thought that the town will have at least one thousand inhabitants during the coming summer.

MR. GEORGE WESTFALL has been appointed superintendent of the Globe Consolidated mine in place of John F. Jewell, resigned. Immediate steps are being taken to crowd the erection of the new pumping machinery with all possible energy.

MR. POWERS has bought the King mine, in Stoneman, Pinal county, Arizona, for \$200,000, one-half cash and the remainder in installments, a condition of the purchase being that the buyer is to put up a mill in connection with the mine.

It is reported that the Bear river iron mines, located about forty miles from Sacramento, and owned principally in that city, prove to contain large amounts of that very valuable substance, tellurium.

A RICH gold lead, thought to be the richest ever struck in Southern Oregon, has been discovered in Rogue river, in Josephine county, about fifty miles below Jacksonville, and assays about \$500 to \$1,100 per ton.

THE companies on War Eagle mountain, Idaho, who are largely in debt to the employees for wages, propose to lease them the mine for a limited period, allowing them the entire product to liquidate their claims.

On the Florida mine grading preparations for first-rate hoisting machinery is now going forward energetically, the present donkey engine not being of sufficient capacity to do the requisite work.

THE Carson Tribune says that Senator John P. Jones has purchased the controlling interest in the Eureka mill, the largest and perhaps the best situated on the Carson river.

THE new coal mine in Coos county, Oregon, being developed by C. B. Jones, is said to promise to be equal in value to any in that section.

THERE are only two Chinese as yet in the Black hills, and they, of course, are running the "washee" business.

PROSPECTING the 1600 and 1700-foot levels of the Crown Point mine as yet affords no new or important features.

No man or woman is safe while the least remnant of cough or cold, or any symptoms of pulmonary disease, lingers in the system. Expel the cause of danger with RAY'S HONEY OF HOREHOUND AND TAR. Pike's Toothache Drope cures in one minute.

(Continued from Page 85.)

level, running the north cross-cut, which is being advanced rapidly. The chlorides continue steadily at work in contracts taking out ore.

EUREKA DISTRICT.

STRIKE IN THE JACKSON.—Eureka Sentinel, Jan. 28: We are creditably informed that a body of fine ore has been struck in the Jackson mine, in the southwest side drift from the tunnel running from the shaft towards the Phoenix ground. The drift at the shaft is 300 ft from the top, but as the side drift runs into the hill, the new discovery is perpendicularly a considerably greater distance from the surface, and is immediately under the old ore body which rendered the mine so famous several years ago. We are not informed as to the magnitude of the body, but hope to be enabled to inform our readers in a few days.

CHERRY CREEK DISTRICT.

MINING INTELLIGENCE.—White Pine News, Jan. 22: The following intelligence comes to us from this mining camp: The Teacup is working its full complement of men, and the mine is producing large quantities of high grade ore. The mine belonging to the company has been only a few days in operation, and the ore is being shipped to the other mines in the district. The Star company is vigorously pushing the drift running west from the 370-ft level, and is taking out ore that strongly resembles the Austin sulphate ore both in appearance and richness. They are also sinking below the 370-ft level in good ore. The active operations that are going on in the different mines has produced a marked improvement in all kinds of business, and the community seem to be well contented with the future outlook.

WARD DISTRICT.

Rich Rock.—White Pine News, Jan. 22: We have been shown some very rich rock just brought in from this immensely rich mining district, which assays "way up" in the thousands. The specimen shown us was from the Paymaster mine, and is the richest silver specimen we have seen in many a day, and the party having the specimen says that there is lots more in the mine just like it. The Paymaster company only shipped just enough of their good ore to pay current expenses, and the balance is sacked and piled away in the mine. The bullion shipments from this district will be very large when reduction works are erected and working commences, which will probably be next summer. All the mining news we receive from this district is of the most flattering character.

Colorado.

TAYLOR'S MILL.—Colorado Miner, Jan. 23: The fine mill recently erected by Messrs. Taylor & Son, for the concentration of low grade ores by the Krom, or dry, process, started up this week, and appears to be doing admirable work and doing it rapidly. From what we have seen of the operations thus far we are prepared to record our belief that the process will prove an entire success.

The ore market is tolerably brisk just now. The Judd & Crosby works and the Pelican mine are running full blast; the Silver Plume concentrating company's works and the Taylor works are busily engaged separating the valuable minerals from low grade stuff that has been hitherto practically worthless; the ore buyers for other markets are doing their full share of work; and everybody seems hopeful and happy and everything prosperous and promising.

The Centennial year comes in with encouraging news from all parts of our mining districts. The amount of supplies going up to the mountains shows that lively work is going on in all the camps. Some new strikes are reported on Kelson mountain, which promise high yields during the season. As soon as the snow goes off, a host of prospectors will dot the hitherto neglected slopes on Silver creek, where the recent strikes in the Wall Street and one or two other mines give promise of as rich and prosperous a mining camp in the near future as prospecting has developed on Democrat mountain within the past two years. Old mines will be worked with heavier forces and good machinery, and many comparatively new mines will be worked with energy this season, upon which only development work has been heretofore expended. Never in the history of the county has there been a time when our miners felt more sanguine of a busy and prosperous season ahead than they do now.

Idaho.

OWHREE COUNTY MINES.—Idaho Statesman, Jan. 25: From Mr. Wm. B. Thoms, time keeper at Oro Fino mine on War Eagle mountain, who arrived here on Sunday evening, we learn the following concerning mining operations in Owyhee county: The Oro Fino mine, with P. F. O'Connell, superintendent, has been working about a hundred men, and has been taking out from 55 to 60 tons of ore per day, till the 10th inst., when work was partially suspended. Operations will be resumed on this mine in a few days. The ore which has been taken out of the first and second levels south is good, gold in the rock being visible to the naked eye. Some of the rock assayed as high as \$300 to the ton. The mine is in good working condition, and the ledge below the third level ten feet in width and the rock of good quality. The company intend sinking on this ledge as soon as operations are resumed.

Mr. Baldwin is superintendent of the Golden Chariot mine. The mine started up about the 10th inst. Much labor has been done in clearing out the water with which the mine had been filled. The water is now nearly all out, and rock is being taken out of the 9th and 10th levels. About 40 men are employed.

Captain Bledsoe has received the appointment of superintendent of the Poorman mine as successor to Dudley Hoyt. The intention is to settle up the indebtedness and work the mine extensively under the new management.

The above are the only mines upon which any work is being done. About one hundred men have been obliged to leave camp on account of the suspension of operations on the other ledges. All are hopeful, however, that work will be resumed on all the ledges before spring and will be prosecuted more vigorously than ever before.

THE ATLANTA COUNTRY.—Idaho Statesman, Jan. 22: The Wide West, at Red Warrior, shut down last week. This was occasioned by the mill being out of repair, the heavy expense of running the mine when not fully prepared, and the necessity of Mr. Hussey going East. He has gone East to procure means to work the mine properly, and expects to be back by the first of April, and to be prepared to prosecute work vigorously and successfully. At Atlanta mine, where the progress is satisfactory, and a most brilliant season. The Monarch company's Atlanta is still yielding rich shipping ore in abundance. Their mill is running constantly on third-class ore. The Buffalo company are getting good ore from their Atlanta. Their ledge will be tapped soon by their lower tunnel, which they have been running now for four months, being some 300 feet in length.

Captain Baxter & Co. are preparing work on the Leonora, and recently have been getting some magnificent specimen ore; they have some 700 tons in sight that will mill from \$25 to \$30 per ton. They are now connecting their lower tunnel with the shaft from the surface and the workings, so as to get this ore out; intending this tunnel to run in further, and they will have backs of ore to keep a mill running for a year or two. They were kept back on account of not getting their supplies in, and consequently are going slow this winter.

IDaho CITY MINES.—Placerville I found to be remarkably dull; snow about four feet deep, and consequently a good prospect for the future; and they anticipate a

prosperous mining season with a bountiful harvest of gold. Every one seemed hopeful of better times coming.

At Quartzburg I found things very quiet, nothing going on but the operations of the Gold Hill company who are working the tail force of men and taking out what they term first-class ore. They expect to start up their mill about the 20th of this month. When they get to running it will make a great difference in things in that part of the Basin, as they will then disburse about \$5,000 per month.

Oregon.

MINING ITEMS.—Oregon Sentinel, Jan. 19: From parties who have recently arrived from Rogue river we learn that the owners of the Scott mine have sunk a shaft on their ledge to the depth of 12 ft, and that the ledge at this depth is about the same width as when first discovered; that the ore taken out is very rich, and the proprietors are sanguine that it will yield very large returns. The English company at Galice creek have commenced operations, and have been at work about three weeks in the claim formerly owned by Thos. & Co., but have not yet made a clean-up. They have now about 125 men employed, and we expect shortly to hear of their taking out a great quantity of ore. The miners in this vicinity, owing to the recent cold weather, have been compelled to suspend operations, but as the weather has moderated considerably, they are again at work livelier than ever. San. Bowd-nand Wilfer Prefontaine are running two claims with hydraulic apparatus on the right hand fork of Jackson creek, and will no doubt go over considerable ground while the supply of water continues. The Oregon is doing well, and the company have, we are informed, suspended work for the present on the Althouse ledge, but we have not learned the cause of the suspension, which we hope is only temporary. Everything augurs well for an abundant yield of the precious ore in Southern Oregon the present winter, and, as a consequence, during the coming summer money will be more abundant in this country than for many years past, which has been owing to a lack of water with which to work the placer mines.

HEATH DISTRICT.—Bedrock Democrat, Jan. 19: This is the name of the district where the large, rich and extensive silver lodes have been discovered, about sixty miles east of us, immediately across Snake river. There is no doubt but that the mines are good. The camp will be a large one, and its trade will be of great importance to the point that secures it. It naturally tends toward Baker City as the most accessible. The citizens of that district only ask of our people that they will aid in the building of a good wagon road to Snake river—to the ferry—and then their trade will come to us. This is a matter that interests our business men as well as our farmers, and if they wish to secure a good and lasting trade and a market for their surplus farm products, they should aid in the building of the road asked for. The expense incurred for our people would be but small in comparison to the benefits they would derive from the outlay. If they wish to secure the trade they must make some effort to do so—other places are working for it.

Utah.

BINGHAM CANON.—Or. Salt Lake Tribune, Jan. 26: Half the Aladdin mine has been disposed of to Chicago parties. Thirty thousand dollars, it is said, was the consideration. If so, it is cheap at those figures. This is a good beginning for 1876, and an indication of the whole year.

The Winnamuck whistle awakes the echoes of the Ogkib. The latest machinery works smoothly, and the rock in the shaft is favorable to rapid sinking, and everything looks encouraging.

Despite the intense cold of the past week, a few of our placer companies are washing with good results. Gravel in some cases is being piled up to be run through the sluices in the spring.

The English placer company are now in 360 ft with the Winnamuck ledge. They are running in very good drifting ground, and have been fortunate in not having encountered any logs or very large boulders.

CONSOLIDATION.—There has been a rumor on the streets for the past week of a big consolidation of mining interests in Little Cottonwood, which, it is said, will engulf nearly all the mines on Emma hill. As far as can be gathered, it is a consolidation of the Emma Hill Consolidated mining company's claims with the North Star mine, recently purchased by Mr. Honore, of Chicago and others. There have been rumors of the Emma mine being also included in this gigantic enterprise, though that may be considered with allowance. There is no doubt that there is a powerful combination at work to effect the consolidation of the prospect in the future, to effect the Vallejo, South Star and Titus and Elmer mines, as they are all supposed to be on the same vein as the North Star, and within the ground claimed by it.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. W. RILEY—San Francisco.

PACIFIC RURAL PRESS.

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, \$4 a year.

DEWEY & CO., Publishers,

No. 224 Sansome street, SAN FRANCISCO.

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874.
MESSRS. DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of the most stand in their own light when they do not put their business into your hands.
I remain yours truly, A. M. GASS.

GIVE YOUR FULL ADDRESS when you communicate on business to this office, especially in returning newspapers. The fact that your name is on our subscription list is of no assistance to you. Without sending your post office address we should have to look over thousands of names to find yours.

THE MINING AND SCIENTIFIC PRESS is the leading journal of America. New processes and mechanical inventions are illustrated and discussed in its every issue. It is a 16-page sheet, handsomely printed, for \$4 a year. Dewey & Co., publishers, San Francisco. [Mt. Lincoln News, Alma, Colorado.]

A REAL CONVENIENCE.—DEWEY & CO: Please send me the RURAL PRESS. It is a real convenience and I cannot do without it. Enclosed you will find five dollars. Fraternally, B. F. E. K. Anaheim, Cal., October 12, 1874.

DEWEY & CO.**American & Foreign Patent Agents.**

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our moderate prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

UNITED STATES**Mineral Land Laws, Revised Statutes,**

And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Official Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

Dewey & Co. { 224 SANSOME ST. } Patent Agt's.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cherokee Flat Blue Gravel Company.

Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte county, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 35) levied on the twenty-eighth day of December, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
O. Waller.....	1	624	\$31.20
Lonis Schmidt.....	2	128	6.40
E. J. Pfeiffer.....	10	480	24.00
A. Cassell.....	17	4,608	230.40
Mrs E. M. Walton.....	21	128	6.40
Mrs Mary W. Farrington.....	35	144	7.20
Geo W. Ramage.....	36	320	16.00

And in accordance with a resolution of the Board of Directors, made on the twenty-eighth day of December, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, room 13, No. 328 Montgomery street, San Francisco, Cal., on Saturday, the nineteenth day of February, 1876, at the hour of one o'clock, a. m., of such day, to pay delinquent assessments, together with costs of advertising and expenses of the sale.

O. H. BOGART, Secretary.

Office, Room 13, Safe Deposit Building, San Francisco, Cal.

Eureka Stone Manufacturing Company.

Location of principal place of business, San Francisco, California.

NOTICE is hereby given, that at a meeting of the Board of Directors of said company, held on the twenty-sixth day of January, 1876, an assessment (No. 3) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the company, No. 567 Market street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-second day of March, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

P. D. MOWELL, Secretary.

Office, No. 567 Market street, San Francisco, Cal.

Moore's Flat Blue Gravel Mining Company.

Principal place of business, San Francisco, Cal.

Location of works, Moore's Flat, Nevada county, Cal.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 26th day of December, 1875, an assessment (No. 1) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary at the office of the company, room 1, No. 531 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 10th day of February, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 22nd day of March, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WM. SMALL, Secretary.

Office, Room 1, No. 531 California street, San Francisco, Cal.

Union Stone Company of California.

Location of principal place of business, San Francisco, Cal.

Location of works, San Francisco, Cal.

NOTICE is hereby given, that at a meeting of the Board of Directors of this company, held on Wednesday, the fifth day of January, 1876, an assessment (No. 3) of twenty cents per share was levied upon the capital stock of said company, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 19 First street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Tuesday, the eighth day of February, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 22nd day of March, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

R. E. KNOX, Secretary.

Office, No. 19 First street, San Francisco, Cal.

DIVIDEND NOTICE.

San Francisco Savings Union, 532 California street, corner Webb. For the half year ending with December 31, 1875, a dividend has been declared at the rate of nine (9) per cent. per annum on Term Deposits and seven and one-half (7½) per cent. on Ordinary Deposits, free of Federal tax, payable on and after January 12, 1876. By order of
LOVELL WHITE, Cashier.

DIVIDEND NOTICE.

California Savings and Loan Society, 512 California street. The Directors have declared a dividend of nine and six-tenths (9-6/10) per cent. per annum on Term Deposits and eight (8) on Ordinary Deposits, for the half year ending December 31, 1875, free from Federal tax, and payable on and after Saturday, January 8, 1876. By order
D. B. OHLSOHL, Secretary.

Placer Mining Outlook.

After a careful survey of the field, and with reports from all parts of the county, says the *Placer Argus*, we feel justified in claiming that the mining prospect is decidedly better than it has been for many years. The yield of gold in this county will undoubtedly be larger than it has ever been, except in the flush days of placer digging.

Our quartz mines are undeniably in splendid shape. The St. Patrick and Ophir made a clean-up at the close of last month that, after paying for its expensive new machinery, placed it out of debt, and gave it a handsome surplus to begin the New Year. Its stopes are yielding abundant ore of a high grade to keep the mill running all the time, and there is ore in sight to keep this up for more than two years. Next month will in all probability yield the stockholders a dividend, to be followed regularly thereafter by a handsome return for their investment.

The Bellevue is not now in operation, but its owner, George D. Aldrich, is confident that the mine is of great value, and he will soon take steps to make it productive.

The Good Friday is yielding large quantities of rich ore, and the owners feel sure they have found their bonanza.

The Julian, near Newcastle, is steadily driving ahead, and is paying its energetic proprietors well.

The Rising Sun, at Colfax, continues to pay dividends, and is a source of permanent wealth. Numerous ledge are being prospected in various parts of the county, and while it is not expected that all of them will grow rich, good strikes are being reported, and considerable gold is being gathered from them.

It is our gravel mines, though, that Placer county must look to as its chief source of wealth, and from these storehouses the principal yield of treasure will flow. At Dutch Flat and Gold Run, the extensive tunnels that have been driven through the mountains at great cost are about completed, and are now in use. By their aid the great beds of blue gravel of fabulous wealth are now being worked, and we do not doubt that the amount of gold taken out at those points will far exceed the yield of any previous year. The business of both these towns is feeling the impetus and prosperity is sure to come. The two great water and mining corporations, the Cedar Creek company and the Gold Run ditch and mining company, are both preparing for extensive improvements. They have acquired Summit valley, and will next season erect the largest reservoir in the State.

At Iowa Hill and vicinity work is going on with vigor. The finest mines in the county are to be found there, but heretofore the want of water has prevented their profitable working. Now this difficulty has been overcome, the rich beds of auriferous gravel will yield untold quantities of the precious metal.

At Michigan Bluff, Forest Hill, Yankee Jims and all along that divide, everything is alive. New claims have been developed, and old ones that in times past have proven rich are being refitted, and with the abundance of water that we are receiving, the prospect is bright with promise. Nor is the more primitive style of mining entirely done away. Quite a good many men are profitably employed in placer mining, and are meeting with good success. We have chronicled within a few weeks the finding of several nuggets varying in value from \$17 to \$100, and the yield of finer gold from this source is considerable. Taken altogether the new year is bright with promise, and should not come unforseen change take place, we may count on a revival of business that will gladden the hearts of thousands.—*Placer Argus*.

THE ENGLISH CHANNEL TUNNEL.—Since the failure of the Bessemer swinging cable steamer and the double keeled *Castalia*, increased attention seems to be drawn toward the proposed tunnel, as the only practical solution of an easy channel passage. Some time ago a preliminary shaft was commenced near the shore on the English side, and now a similar work has been commenced on the French side of the channel. The depth of this latter will be 328 feet—about half the utmost depth which it is supposed the tunnel will require. The object of these shafts are to prove by ocular demonstration, *in situ*, whether the geological formations at certain depths agree with the theory of the scientists. The feeling is certainly gaining ground that such a work is needed and will pay as an investment; and if the two shafts, when completed, should develop the expected facts, the project will be considered practical, and then nothing will be left but to provide the millions of pounds sterling required to carry out the idea. This latter provision will be a difficult one to realize; but it is not beyond the possibilities of a proper combination of English and French financial enterprise.

CHINESE IMMIGRATION.—In Congress, the House Committee on Foreign Affairs, though opposed to the joint resolution of Representative Piper requesting the President to use all expedient means to have the existing treaties of our Government with that of China, so modified as to prevent the further immigration of subjects of that empire to the United States, have consented to withhold a report to the House until the reception of the resolutions of the California Legislature on that subject.

It is rumored that the Occidental and Oriental steamships will withdraw.

BLAKE'S PATENT STEAM PUMP

Over 8,500 in Successful Use in the United
States.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, dying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

Hoisting Engines. Mining Engines.

TREADWELL & CO.,
San Francisco.
Are the only Agents for sale of these Engines in the Pacific States.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)
Our new Mining Engine is built from plans and specifications of several of our most successful MINING ENGINEERS, and the result is the most complete

Double Drum Hoisting Engine

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

TREADWELL & CO.'S,

SAN FRANCISCO.

Alden's Ore Crusher and Pulverizer.

to run, only \$1,200. For particulars address
FARRELLY ALDEN, Patentee and Manufacturer,
25 Fifth Avenue, Pittsburgh, Penn'a.

Now pattern as here shown, is claimed to reduce as much gold quartz to dust, and that without the aid of a preparatory rock breaker, as 20 to 25 to 1. The engine is 8 to 12 ft. P. H. and 18 to 24 in. diameter. It has 2 counter-rotating shafts, yoked together, that crush and grind continuously at both forward and backward motion. The capacity is 2 to 3 cubic feet per minute. It is easily handled, the total weight, 2,423 lbs. (total 18,000 lbs. Whole cost, complete body

Valuable Improvement in Pumps.

We illustrate on this page two styles of pumps for continuous discharge, with respectively three and four cylinders. The special object of this improvement is to cause the pump to throw a full and rapid stream of water continuously and with uniform velocity. Mr. A. J. Smith, 222 and 224 Fremont street, invented this pump and applied for a patent thereon, but finding that he had been anticipated by another inventor (S. D. Lount, of Chattanooga, Tenn.) he has purchased the right for this coast, and is now manufacturing the pumps in various styles and sizes.

The pumps are made in the peculiar manner shown in the illustrations, in order not only to effect a saving of power, but also to keep the stream of water in a continuous motion and avoid the jar and strain which, as is well known, occurs in ordinary single cylinder pumps.

The construction, as will be seen, is quite simple. The power is applied in the ordinary way. In Fig. 1, *D* is the feed pipe and *E* the discharge pipe. *A A A A* are the cylinders, *C C C C* are the valves, and *B B B B* the passages by which the water passes from one cylinder to the other in its continuous motion. As the crank shaft revolves the pistons operate in the usual way.

It will be seen that the cranks are arranged in Fig. 1 to follow each other at intervals of 90 deg. The object of this construction is that the water may always be impelled by that crank which is moving up or down most rapidly at any particular time, while those cranks which are passing the dead points shall have ceased for the moment to have much, if any, effect on the stream. In this manner the water is forced along at all times by that plunger which is at or near its maximum speed; the others meanwhile moving back in turn to take their places for another throw. In every case the lifting or forcing power is necessarily applied by the most rapidly moving piston, and this water driven by this piston faster than the other pistons are moving, opens their valves and passes along without obstruction from said pistons, although all are virtually operating in the same cylinder or water passage way.

Mr. Smith also makes these pumps with three pistons, as shown in Fig. 2. In this case the three pistons are arranged in single cylinder, one over the other, to operate in the same way as with four cylinders. With three cylinders, however, the cranks follow each other at intervals of 120 degs., the passages, *B B*, being arranged to carry the water from the top of one cylinder to the bottom of the next. In this figure, *A A A* are the cylinders; *B B* the passages connecting them; *C C C* the valves; *D* the feed pipe, and *E* the discharge. The three cylinders are but parts of one passage way for the water and the three pistons all operate upon the same stream, keeping it in continuous motion.

It will be seen that after once starting the pump the stream is kept continuously flowing, and there is no "thud" or jar as in ordinary single cylinder plungers, which have to start the stream anew at each stroke of the piston. Any one familiar with the action of pumps, knows that this causes the greatest strain upon the valves and cylinder, and also limits the throwing capacity.

In the three and four cylinder pumps, as the valves open and close, when relieved from pressure, they are able to do a large amount of work with little or no wear and tear. They are especially adapted to pumping to great elevations, which in mining work is an essential feature. Mr. Smith says he can make them to raise water three or four thousand feet at one single lift, and thus do away with the great number of pumps which are now required to raise water that distance in short lifts of two or three hundred feet each.

For windmills, this continuous action motion is also very advantageous, as it will run slow or fast, without any jar or jerking motion. For irrigation, pumping in large quantities, it is claimed that it will pump with greater economy, as wind power is variable and unsteady. Mr. Smith informs us that he is about to

construct a pump and windmill complete, which will be capable of pumping 20,000 gallons per hour to a height of 100 feet, at a cost which need not exceed \$1,500. In this connection we are referred to this work done with these pumps by Louie & Co., Italian gardeners on the Hudson tract, South San Francisco, where there is a three cylinder pump

stroke. Running 50 strokes a minute, it raises about 4,000 gallons an hour. Its construction is somewhat different from those illustrated here.

The qualities mentioned above make this pump also invaluable for pumping by horsepower, as it makes as even work for the horse as hauling a load on a smooth rail. The

FIG. 1. FOUR CYLINDER CONTINUOUS ACTING PUMP.

at work (5x8) in place of a three and one-half inch chain pump, and from which Mr. Louie asserts that he is getting nearly three times the water which this chain pump furnished him with the same windmill. There is a pump

Fig. 2. Three Cylinder Pump.

constructed on this principle at the Chicago brewery, placed 60 feet deep in a nine inch well, and pumping the water 70 feet above the surface, or in all about 130 feet. The size of this pump is four inch diameter, eight inch

smoothness of the operation enables the horse to do more work than he could if compelled to undergo a continual jar and hammering, which the single cylinder pump necessitates. Mr. Smith asserts that this pump can be run up to the same piston travel as the steam engine.

The pump we saw in operation at Mr. Smith's shop has four cylinders, two inch bore and two inch stroke, the same as that shown in Fig. 1. When we saw it in operation it was running 150 strokes a minute, under 500 pounds per square inch pressure, equal to over 1,000 feet elevation, and there was no perceptible noise or jar whatever. The stream from the discharge pipe flowed steady, with no break or eputter.

A NEW STEAMBOAT BOILER.—The Government Board of Supervising Inspectors of Steam Vessels, in session in Washington, has authorized the use on steamers of twenty-five tons burden and under of a new boiler, provided its pipes shall not exceed two inches in diameter. This boiler is the invention of Mr. Harnesboff, of Rhode Island, and is composed of coils of iron pipe enclosed in outer casing; the coils are set over an ordinary grate; the feed water is forced into the upper-end coil and is converted into steam in its descent; the steam is conveyed into a receiver outside the boiler, from which it is taken to the engines. The lower end of this receiver is supplied with means for blowing out sediment that may be collected. The board was satisfied with the utility of this boiler for marine purposes, within certain limits of construction, as given above. It is thought that the boiler can be used successfully and safely on the smaller class of steamboats, such as ply upon our rivers.

A BILL has been introduced in Congress declaring the Reading military reservation, in Shasta county, California, subject to pre-emption and homestead entry.

Quicksilver Furnaces.

[Written for the Press.]

It is certainly a strange but incontrovertible fact, that with all the advance made in applied chemistry to the arts and sciences, the manner of building quicksilver furnaces should remain almost in the same state for years and years, little or no improvement being made in them.

It is true many modifications have been made, but still the principle is adhered to that has been in use in Almaden (Spain) for years past—that of treating a valuable ore of metals in the same manner that limestones are burned, by passing the fire directly through the mass—with what result, those who have given any attention to the matter know too well, the product bearing no proportionate result that should be obtained by proper manipulation.

The only improvement—if such it can be called—made on the old manner of working, is that instead of being intermittent in charging and discharging the furnaces, it is now made continuous; but still this barbarous treatment of the ore is continued by "burning the rock," properly so called; for the object does not appear to be how to obtain the quicksilver, but how much heat can the ore be made to bear. Now, no one doubts that every particle of the ore has been thoroughly burned, and the sulphide decomposed, but where is the quicksilver? Certainly the amount that should be in the condensers is not to be found in them; and its place is occupied by a white substance, mixed with the material usually called soot, and both are, as a general thing, lost in washing.

From a series of experiments, made some years since in Almaden, Spain, extending over a period of six months each, the best results obtained were 60 per cent. of the assay value. Upon these results being known, they adopted retorts for working the cinabar, and thereby much better results were attained. Now, this certainly demonstrates one thing, that the crude and unscientific manner of treating the ore, (in a lime kiln fashion), had this one great defect, that the loss of metal was and still is very great and ruinous; but when the ore is rich, the production of quicksilver is so abundant no notice is taken of this waste of metal. These facts remain at this present time where the manipulation of the ore is carried on in the same manner or the modifications mentioned.

It is now proposed to show how, where and under what condition this loss occurs: The combustion of sulphides produces, by the action of air and moisture, sulphuric acids—in fact, it is produced without the aid of the moisture, from the presence of sulphuric anhydride, and taking the oxygen from the ferric and other oxides formed. The action of this hot sulphuric acid on the finely divided mercury, as it is eliminated from the ore, causes the metals to be vigorously attacked and converted into a sulphate, and this substance is carried along by the draft and deposited in the condensers, combining with the soot, and as a general thing washed away, thus occasioning the great loss referred to. As a further proof of the abundance of acid formed, this destruction of the iron condensers, now in use, fully demonstrates.

CINNABAR.

JUDGING from the glowing reports published in the Eastern newspapers the Black hills diggings are turning out well. Twelve hundred men are said to be taking out \$1 per hour on an average to each man on Rapid creek, while four men in six hours recently took out \$137, and on the following day, at the same place and time, \$112. Nuggets worth \$20 and \$25 are not uncommon, and the field grow richer every day. The Indians, however, threaten trouble in the spring.

FLUCTUATIONS IN PETROLEUM.—Great have been the fluctuations in the price of petroleum. Since 1864 the monthly price at Titusville has been all the way from \$13.75 to 73 cents per barrel, and the average of prices has been from \$7.62 in 1864 to \$1.29 in 1874. Fortunes have been won but few have been kept. The suddenness with which those who were poorest of the poor have become millionaires, has only been equaled by the suddenness with which they have become poor again.

The Smelting Ores of Inyo Co.

A correspondent of the *Chronicle* says: The masses of the State have but little idea of the vast mineral resources of Inyo county, and hundreds of men have visited the county on running visits in the last five years that have not the least idea of its mineral wealth. The excitement of 1862 caused an investment by outside and reckless capital in mills and machinery, erected at a cost of about \$2,000,000, in a hurried and insane effort to reduce rebellious copper-bearing ores—an effort that was futile, of course. The failure was a complete check on the county for nearly ten years, until men of energy and enterprise uncovered the riches of the lead and silver bearing mines of Cerro Gordo. This was done with little or no outside capital; the few that personally took hold of the enterprise commenced poor, discovered after many failures the proper mode of reduction, and in a few years made themselves rich and brought wealth to the county, until to-day it can truthfully be said that there are more men of substantial means in Inyo county than in any other county in the State in proportion to the population. To-day Inyo's greatest promise is in

Her Lead Ores.

As such ores are found in almost unlimited quantities, and the method of reducing them with a large margin for profits is well understood. If the Fryer process becomes a demonstrated success, so it can be used without too large a royalty to the patentee, and even if it is a success at a cost of eight times the assumed expense of reduction of rebellious ores, Inyo will be able to turn out from her rebellious ores more silver than from her galena ores that are now giving her a reputation as a mining county. I notice that the "mineral statistics" of the coast gives Inyo county credit for a product of \$2,000,000 of silver bullion for the year 1873. The public may be surprised when I inform them that this product was the result of smelting by two small furnaces only, and from a mine that to this time has been developed to the depth of only 500 feet, with only one year's product out of four accounted for. The discovery of lead mines in and about Darwin within the last fifteen months has brought to light great deposits of ores as easily reduced by

Smelting as in Cerro Gordo.

That are capable of increasing the annual product of silver in Inyo an hundred fold. To say that Inyo county could ever produce \$200,000,000 of silver bullion annually may seem to be stretching the truth; but it is not without bounds. Let Cerro Gordo mines be examined; they have already furnished the proof of \$2,000,000 annually; then contrast them with the mines of Darwin, and any one with ordinary calculation will say that with the same management and energy given in working the Darwin mines they will without question increase the product an hundred fold. Three furnaces are to-day running at Darwin. I am told that they produce each 200 bars (of eighty pounds to the bar) lead bullion per day, of an average assay value in silver of about \$300 per ton. If these enterprises are not profitable it is because they are run by incorporations that call for a dividend on stock issued to the amount of \$10,000,000 in each enterprise. Defiance mine is running one furnace, the ore smelted is mined by three men, and twenty or fifty men employed on the forty-foot vein exposed could mine ore sufficient to produce 1,000 bars of lead bullion daily.

Yuba County Gravel Mines.

A correspondent of the *Resources of California*, writing from Smartsville, Yuba county, says: This is indeed a smart mining camp—a good, lively, prosperous, and very promising town, of say 600 people, located just in the foothills, half way from Marysville to San Juan North, 20 miles from each place, 14 miles from Wheatland, 16 from Grays Valley and 18 from Nevada City. This is purely a mining town—its interests absorbing Timbuctoo, about one mile west, Mooney's Flat, one and a half miles east, and Sucker Flat, one and a half miles north. Smartsville is growing—new houses are going up and old ones are being repaired. While the business of the other little places named has been concentrated in Smartsville, they are still the residence of many families, being convenient to the mines. The location of Smartsville is pretty. It is a cheerful, pleasant place, with two churches, a nice public school, costing \$5,500, including house and grounds, with a library of 400 volumes, and ably managed by three efficient teachers, on salaries of \$100, \$70 and \$60. Here are 234 census children. The town has two hotels, two stores, two drug stores, two livery stables, one meat market, one tin and stove store, one blacksmith and wagon shop, one shoe shop and one barber. This town has boasted of eight incorporated mining companies. It is all hydraulic mining, and the operations are among the most gigantic in the State. To indicate the value of these claims, we will state that the secretary's books show that from Timbuctoo to Mooney's Flat, in a space of less than two and a half miles, there has been taken out nearly \$30,000,000; and if the gigantic operations already inaugurated and in process of construction, be carried out, fifty years of incessant labor will not exhaust these great and rich gold bearing gravel beds.

The Blue Point mining company have run a tunnel 2,270 feet, to run the gravel through, at a cost of \$146,000. This claim has paid as

high as \$2,300 per day, and has paid \$18,000 in dividends monthly.

The Bline Gravel mining company has run three tunnels, costing \$75,000, \$60,000 and \$50,000 each, about 1,600 feet long. They have taken out as high as \$2,000 a day, and have paid in all, \$800,000 in dividends.

The Rose Bar mining company have just completed a tunnel 1,400 feet long, which cost \$80,000, and have now commenced an extension 150 feet long, with a branch tunnel 600 feet long, using the new diamond drill cutting out a core of the rock. It drills one and a half inches in a minute by water power.

The Smartsville hydraulic mining company have taken out \$550,000. They will have to run a bedrock tunnel, or work through another which they can purchase.

The Pactolus mining company have run a bedrock tunnel 1,300 feet, costing \$60,000. Their claim pays \$800 a day every day it is worked.

The Enterprise mining company run a tunnel 80 feet above the bedrock, which cost \$60,000. The dirt washed through this tunnel pays well. They intend to run a bedrock tunnel.

The Deer Creek mining company, at Mooney's Flat, are running a tunnel 3,500 feet long. They are in 1,000 feet, making, through very hard rock, with the Ingersoll drill, 20 feet per week, in a tunnel eight by eight. This company's claim embraces 350 acres of rich gravel.

One of the largest and heaviest operators in the State is the Excelator water company, J. W. Pearce, president; Geo. P. Thurston, secretary, office, 313 California street, San Francisco; E. S. Thurston, engineer and secretary at Smartsville. This company owns all the water right here, having 110 miles of canals and ditches, with a carrying capacity of 8,000 inches, miners' measure. They bring to this place an average of 5,000 inches per day. They bring their water from Deer creek, Squirrel creek and the three Yuba rivers. They sell \$150,000 worth of water per year, at ten cents per inch, or for irrigation at \$10 per acre. This company own all the mines at Timbuctoo, seven-tenths of the Deer creek company's claims, three-sevenths of the Blue Point company's claims, three-fifths of the Smartsville hydraulic mining company's claims, besides other smaller interests. They have an iron pipe forty inches in diameter one and a quarter miles long, costing \$60,000. They own twenty-five miles of telegraph line, running to various points in these claims. They have just purchased 2,000 acres of land below here on the Yuba, and intend to irrigate and cultivate it, and will go largely into fruit, especially semi-tropical fruits.

On the Empire ranch, one mile above town, Mr. Thomas Mooney's, we saw several hundred fruit trees growing, all the northern varieties and some of the semi-tropical doing well. This ranch embraces 240 acres, 200 susceptible of cultivation. It is devoted principally to hay. We have been much interested in our visit to this mining town. An excellent road from Marysville and a splendid line of stages therefrom and only twenty miles distant affords a rare opportunity for any one to see some of the heaviest mining operations in the State. The gold bearing gravel channel here is a very hard cement, which requires blasting before hydraulic mining, and as high as 2,200 kegs of powder have been charged in one blast. Some government land can be bought at from \$5 to \$10 per acre. At least sixty acres of a quarter section on an average will be found suitable for cultivation and the rest for grazing and wood. Here is plenty of water for irrigation. Those who have tried it say they can make money on every acre they cultivate, even by paying \$10 per acre for a year for irrigating their lands.

The Mines and Workmen.

We understand that quite a number of the prominent miners of this camp, backed by responsible merchants, have made a proposition to the companies interested to lease some of the mines on War Eagle mountain, in order that the workmen to whom the companies are largely indebted can have an opportunity to make subsistence for themselves at this unpropitious season of the year. The companies will be subject to no sacrifice in acceding to this arrangement. On the contrary, they are liable to be gainers, as we understand that the parties who propose this thing are willing that the surplus proceeds from their operations shall be applied to paying off old claims or cancelling the most urgent debts in which the companies are interested. The closing down of many of these mines is liable to be attended with most disastrous consequences, as workmen are unable to get away from the camp, and must soon be in want, unless something is done for their relief. Added to this, business of all kinds is liable to come to a standstill. There are responsible men here who are willing to make some sacrifice in order to show that the cause of recent drawbacks is not in the mines themselves, but in their defective management. There are now several hundred tons of rock at these mines on War Eagle mountain awaiting crushing, and with what can be taken out during the winter months, we are satisfied that sufficient bullion can be produced to keep the camp in a comparatively good condition for the remainder of the winter, as well as assisting the companies in the removal of incumbrances that now exist.—*Idaho Avalanche*.

SENATOR JOHN P. JONES has purchased the controlling interest in the Eureka mill, the largest on the Carson river, and by many considered the best in the State.

The Mining Debris Question.

In the last issue of the Oroville (Butte county) *Mercury* was published the memorial and resolutions introduced into the Assembly by Mr. Berry, of Sutter county. They have appeared in nearly every paper published in the agricultural portions of the State, and in a few of those where mining is carried on. The memorialists claim that all of the overflows and the filling up of harbors is caused by mining, and that therefore Congress should pass laws allowing mineral lands to be disposed of for the purpose of hydraulic mining, only upon such conditions as shall prevent injury and damage to the valley lands, rivers and bays of our State. By means of just such reckless statements as are contained in the memorial referred to, a large number of the people throughout the State have come to the conclusion that the mines are about exhausted, or at least that the gold taken out is of far less value than the injury done to land, rivers and harbors. The statement therein contained of the destruction of lands and the value thereof is wide of the mark. There is not a single man living in the vicinity of the lands damaged that will value them at one-half the price set upon them by the memorialists, or who will claim that but little more than half the land named therein has been damaged in the least. A great deal of mining has been done in this county since '49, when gold was first found here. Vast tracts of land have been sluiced away. At Cherokee, a strip over half a mile long, and in some places near 100 feet deep, has been washed away and sent down Dry creek, along the line of some of the best farms in the county. Yet with all the mining done, we can safely say that not over 1,000 acres of agricultural lands have been damaged in the least, and the whole value would not exceed over \$40,000. This, we say, is the extent of damage done in Butte since '49, by reason of carrying on the business of mining. Now let us see what amount of gold is taken out, and then if the injury is greater than the profit, we will join in the cry to shut up the mines, for that is just what the resolutions ask Congress to do.

A few days ago we inquired at the office of Wells, Fargo & Co., in this town, if they had any data by which we could learn the amount of gold dust and bars shipped by them from this place. E. W. Fogg, the agent, kindly furnished us with the following figures: Amount of bullion shipped by Wells, Fargo & Co.'s express from Oroville in 1873, \$1,235,323; in 1874, \$1,470,764; and in 1875, \$978,903; making a total of \$3,674,990 that has been shipped from this little town in three years. And yet Mr. Berry asks Congress to pass such laws as will lay an embargo upon our mines and virtually close them. Let some of our readers may suppose the mines are yielding less now than formerly, we will add that last year being very dry, but little mining was done except in those places where living water could be had. The gold sent from this place is far from being all that is taken out in the county. All of that from Forbeatown, Bangor, Evansville and some from Wyandotte, goes to Marysville and we get no account of it here. We hope our representatives and senator will carefully investigate this matter before voting for those resolutions, for Congress may think they are in earnest, take them at their word and pass the laws asked for, a thing which, if done, would forever seal the doom of this State. Close up the mines and this State would soon sink in rank and importance.

CHALOME VALLEY.—Our old friend, Dan Lee, from Chalome valley, called upon us last week. He informs us that the settlers there feel jubilant over their excellent prospects. They have had their share of the late copious rains, and the hills are clothed with an abundance of feed for stock. The mines of that district are exciting the attention of San Francisco mine dealers and stock buyers. The Nevada quicksilver mining company have a furnace in operation, and it is found that the ore is rich in its yield of mineral. The hill ranges of Chalome, in the estimation of settlers and others, promise very rich developments of quicksilver, coal, iron, gold, silver, manganese and antimony. The indications are favorable to the early extension of the railroad in that direction, as the engineering advantages of the Paronia pass route makes it the preferred route of the railroad company. As soon as the railroad enters Chalome valley, the mining interests of the settlers will prove of great value. The Secretary of the Red Rock coal mining company has issued a large number of shares of stock to the settlers of Chalome and San Luis Obispo during the past month. Samples of the coal have been forwarded to Hollister and San Francisco, and we are informed from reliable sources that this is the best coal discovery made to date on the Pacific slope. Mr. Stone and several men are now tunneling this inexhaustible coal bed.—*San Benito Advance*.

BELMONT MACHINERY.—From what we consider reliable authority, we are enabled to say that the Belmont mining company is having manufactured in San Francisco machinery of sufficient size and strength that will enable it to sink and work the mine to a depth of several hundred feet below the present workings, which is about 500 feet. If the report is correct, and the mine is properly worked, from what we have learned of the property from those who are familiar with it since the first pick was struck in the ground, the Belmont will ere long become favorite stock.—*Belmont Courier*.

The Valley of San Juan.

A correspondent of the *Philadelphia Press* says: It is in the valley of San Juan where the ruins of ancient cities have been recently found, indicating that it was once the home of a people and of a civilization whose history is wrapped up in the unknown past. The ruins of a city are found scattered over a large section of country. Large rooms are often found cut out of the solid rock, and the locations evidently selected and arranged for the purpose of successful defence. Pottery and other useful implements are found in great perfection. The work and style of manufacture indicate a civilization fully equal to that which prevailed among the ancients or in Peru or Mexico at the time of the discovery of the American continent. It may be that these are the ruins of the Aztec race that were supplanted by the savage Indians, who swept down upon them from the North; or it may be that they are the ruins of a race as civilized as the peoples of the Old World, and who had a history, if it were known, as long and wonderful as the history of Greece and Rome.

One of the results of the topographical survey of the country, now in progress, will be to unearth these ruins and, if possible, make certain the character of a people who, however much civilized and enlightened, had a history about which we can only speculate with our present sources of information.

The Silver Districts

In the western part of the San Juan country are most easily accessible up the valley of the Rio Grande. The head waters of this great river are one hundred miles west of Del Norte, in the same range of mountains out of which the waters of the Animas and the south fork of the Gunnison flow south and west to the Pacific. Lake city is the center of the lake district, and is the county seat of Hinsdale county. It is situated on the south fork of the Gunnison, just below the point where Henaou creek comes down from the northwest. High mountains rise up on all sides of the beautiful park in which the town is situated. I was there in October, after the mining operations of the season were mostly suspended. About fifty buildings of different classes were in course of construction, and much life and activity prevailed. The *Silver World*, a good weekly newspaper, is published here, and the ability with which it is conducted has done much to build up the town and induce the development of the mining district. A mile and one-half above the town there is a perpendicular fall in the Gunnison of sixty feet. A short distance further up the stream there is another fall of 80 feet, and still further up, five miles above the town, is a beautiful lake from which the town and district are named. The lake is known on the old maps as San Christoval lake, and was discovered by Jesuit missionaries. The mines of this district are chiefly found along the sides of the mountains bordering on the lake, and on the stream down to and below the town and up Henaou creek, for 20 miles toward the head of the Animas and the Uncompahgre. I spent five days among these mines gathering specimens from some of the best known. The veins generally run from northeast to southwest, are well defined, and many are exceedingly rich in silver. Some of the veins are narrow, but most of them are wider than the mineral veins of Northern Colorado, and the assay value of the ore is nearly 100 per cent. higher on an average. The Hotchkiss mine yields both gold and silver, in about equal parts, and the ore taken from the richest pay streak, five inches wide, will run as high as \$15,000 to the ton. This mine has a tunnel over 120 feet long, and work is now being pushed forward with considerable energy. After a careful examination, I do not believe the Hotchkiss mine is in any way superior to many others in the Lake district.

FROZEN QUICKSILVER.—The last cold snap was the severest ever known in the vicinity of Carson river, a most singular incident being the freezing of the quicksilver in use at the reduction mills. At the Eureka mill, running 60 stamps and situated in a gorge where the west wind rushed through day and night like the current of air passing out of a blow-pipe, it was noticed that the quicksilver pump had ceased to perform its proper functions. The powerful machinery of the pump continued to work, but no quicksilver was raised to the pans on the first floor. After passing through the pans, settlers and strainers, the quicksilver goes down to the lower floor of the mill, and is then collected in a tank about four feet square, from which it is pumped up to renew its round through the pans, settlers and strainers. When the pump failed to bring up quicksilver some of the workmen went down to the lower floor, expecting to find that the tank had sprung a leak. They found the quicksilver all there, however, but greatly to their surprise it was frozen solid. The pump being useless they got a spade and chopped the quicksilver up into cubes, which they then carried up to the pans with ice books.

A DOUBLE-TRACK narrow gauge railway is now being laid in the exhibition grounds at Philadelphia, for the purpose of transporting visitors from one building to the other. The track is nearly six miles in length, and runs close to all the principal buildings. The motive power will be steam, with a dummy engine of improved pattern, and cars of the most luxurious description. These cars will be operated by the West End passenger railway, and a fare of five cents charged for the trip.

SCIENTIFIC PROGRESS.

A Novel Lecture on Electricity.

Prof. Tyndall recently delivered at the Royal Institution, London, a lecture on electricity, which presented some interesting and novel features for the lecture room. The novelty consisted chiefly in simplifying all the apparatus connected with the lecture, so that the experiments could be repeated with such simple and inexpensive appliances as were within the easy reach of any person.

As examples, the Professor did away with brass balls by substituting apples; and instead of insulated glass rods to support them, he employed sticks of sealing wax. When he required a long conductor, instead of using the ordinary brass rods and wires of an electrical machine, he substituted a carrot; and in one of the experiments where two hemispheres were required, he used the halves of a turnip. He said that he did not know what philosophical instrument makers would think of this plan of doing away with the "pomp and circumstance" of experiments by the introduction of simple apparatus—a remark which was received with applause by the majority present.

In the course of his lecture, Prof. Tyndall stood upon an insulating stool, and made his assistant, Mr. Cottrell, who remained upon the ground, pass a comb made of india rubber 20 times through his (Prof. Tyndall's) hair. The lecturer then placed his knuckles near the end of a long wooden lath balanced on the top of an egg, but the hand did not attract the rod. He explained that to get an electrical effect, the electricity upon the comb ought to have been removed by his assistant before each fresh stroke was made through the hair. Mr. Cottrell then made another 20 strokes with the comb through Prof. Tyndall's hair, and passed the comb between his own fingers before each stroke. The result was that the body of the lecturer became so strongly electrified that the wooden lath was attracted and began to spin round when his hand was placed near it. He illustrated the nature of electrical conduction by a repetition of the experiments once made by Stephen Gray. In the course of his illustrations one of the boys from the audience was placed horizontally upon a wooden plank suspended by silk cords; when an electrically excited glass tube was held over the legs of the boy, a lever arm of straw placed near his head, to serve as an electroscope, was drawn down by the induced electricity. In another experiment he held a glass tube near an insulated boy, and the electrical disturbance proceeded through a long copper wire suspended round the theater by means of silk threads until it reached the further end of the wire, which was attached to a gold-leaf electroscope. Every time the glass tube was placed near the lead, the disturbance passed through the wire, and the leaves of the electroscopes diverged. By these and other simple experiments he sustained the interest of his listeners for the hour during which the proceedings lasted.

A Newly Discovered Force (?)

The scientific world, just at the present time, is considerably exercised about an alleged "new force," thought to have recently been discovered by Mr. T. A. Edison, a well known telegraph engineer and inventor, of Newark, N. J. One mode of producing a manifestation of this force is given by the *Scientific American*, as follows:

Upon an insulated table place an ordinary Morse key and an electro-magnet, the coils of which are so wound that no magnetism is produced in its cores by the passage of an electric current. Use for an armature a piece of the metal cadmium, to one end of which fasten a flat spring. The other end of the spring attach rigidly to a standard fixed on the table. Adjust the armature a short distance away from the core of the magnet. The standard is to be connected by wire to one end of a glass rod or tube, say two feet long. The other end of the tube connects by wire with a graphite point (a lead pencil will answer). Another graphite point is connected by wire to a gas pipe or other suitable mass of metal, not in contact with the apparatus; and the two points, in position similar to the arrangement for producing the electric light, may be placed in a box from which light is excluded, but with a hole in the top for observation. Place 10 or 15 Bunsen cells in circuit with the key and the coils in the usual manner. Now, if the key be closed, a spark of considerable brilliancy will be evolved from the graphite points, but possessing no continuity. If, however, (the battery circuit remaining closed), any part of the connection between the gas pipe and the cadmium is broken, and contacts be made either slowly or rapidly between the disconnected points, the spark reappears at each contact.

It is here that the phenomena are surprising, and apparently inexplicable. The graphite is not in the battery circuit, nor in any other. Moreover, it is separated from the rest of the apparatus by the glass tube. This alone would seem to prove that the force is not electrical, at least as the term is generally understood; and when supplemented by the fact that the most delicate galvanometer and the chemicals most sensitive to the electric current fail to note its presence, this conclusion must be accepted.

Many experiments have been made with a

view of obtaining some definite knowledge, but nothing has been developed beyond the facts above stated, and in addition that, like electricity, the new force passes through or over some substances better than it does over others, and also that, as the resistance of one of its best known conductors is increased by length the spark decreases in brilliancy.

All the manifestations thus far obtained have been of the feeblest kind, so feeble indeed that the current cannot be made to make a record sufficient to allow of its use for telegraphic or any other yet known practical purpose.

It does not seem to be either magnetic or electric, although pertaining to the nature of both. Mr. Edison called it "etheric force," but for what reason does not appear. At first, efforts were made to connect it with Reichenbach's "odoric force." It was also referred to what were denominated "weak sparks" of electricity, discovered several years ago, by Prof. Reiss, of Germany.

But the phenomena connected with this new manifestation, when carefully studied, do not seem to admit of either reference, and scientists are inclined to acknowledge that Mr. Edison has really made a discovery which has heretofore escaped notice.

Dr. Beard, however, is inclined to think that the phenomena may be due to a peculiar form of electrical induction, and that it is, after all, only a new phase of electricity. Mr. Edison prefers to consider it rather a new form of heat or light, rather than of electricity.

The weight of evidence, according to George M. Beard, M. D., in the *Scientific American*, is in favor of a new "radiant force," somewhere between light and heat on the one hand and magnetism and electricity on the other, with some of the features of all these forces." He would place it nearer to magnetism and electricity than to light and heat.

One of its peculiarities is that while electricity prefers to pass by points, this new force appears to prefer to pass through or over large surfaces; thus a large surface of tin foil, several inches square, will conduct it from one mass of iron to another more readily than will two points projecting toward each other from the two masses of iron.

It does not respond to any of the physical tests of electricity, except the spark.

It produces no physiological effects upon muscular tissue, as does electricity.

Glass, rubber, paraffine, dry wood, etc., which are non-conductors to electricity, are very good conductors to this new force.

It passes quite readily over non-insulated conductors—as along a wire laid upon the ground.

For this latter reason it was assumed at first that it might possibly be used for sending messages by uninsulated wires buried in the earth or in the ocean. But no facts have been developed which warrant any such assumption. Indeed, as yet, no practical application can be seen for this new force—if such it is. Scientists will watch with much interest for further developments, and it cannot be doubted, whatever the final result may be, that the earliest investigations now in progress must result in an important extension of our knowledge of the phenomena under discussion.

Birds With Teeth.

Late fossil discoveries have fully shown that birds having perfectly developed teeth, in sockets, have existed on the earth. Birds, owing to the destructible nature of their remains, are among the rarest of fossils, and none are known to have existed earlier than during the cretaceous formation, the three-toed footprints found in the triassic being probably all made by the huge saurian reptiles of that age.

The fossil remains of the first species of birds discovered, which were unmistakably provided with teeth, were described by Prof. Marsh, in the *Am. Jour. of Science*, in 1872. One of these specimens was fortunately in a remarkable state of preservation. It was an adult bird, about as large as a pigeon. The skull was of moderate size; the lower jaws long and rather slender, in each of which are twenty-one distinct sockets. The upper jaw also contains teeth. The teeth remaining in the sockets are small, compressed and pointed, are all directed more or less backward, the upper portion being covered with enamel.

The remains of several other species of birds with teeth have since been discovered, the most interesting of which is a gigantic diver. Some of these birds with teeth were such as lived almost exclusively on the water, being provided with only the rudiments of wings, but having powerful swimming legs and feet. Birds with teeth have been divided into two classes—first, those having their teeth in sockets, and second, those with teeth in grooves. All these discoveries have been made in Kansas, by Prof. Marsh and the Yale College exploring party. The fossils have been placed in the Yale College museum.

Methods for hardening glass are now one of the favorite studies of inventors. Mr. Macintosh, of London, finds that by enclosing fused or pasty glass in platinum molds of the desired shape and then suddenly cooling it by any frigorific mixture, the glass becomes exceedingly hard. Glass can be made harder than the diamond, and its powder be used instead of emery powder or diamond dust. Artificial gems of the proper hardness and of adamantine luster can be made.

THE LION "A PRETENTIOUS HUMBUG."—The lion has generally been considered as king of beasts, more probably by reason of his more royal and majestic appearance than in consequence of his superior strength. But the tiger is really the most agile and powerful of the two. This statement is concurred in by all who are intimately acquainted with both animals. It is said that five men can easily hold down a lion, while it requires nine to control a tiger. It is also well known that anciently the tigers almost invariably killed the lions in the amphitheaters. The Rev. Samuel Houghton, in his book on "Animal Mechanics," shows that the strength of the lion, in the fore limbs, is only 70 per cent. of that of the tiger, and in the hind limbs only 60 per cent. The same writer remarks: "The lion is, in truth, a pretentious humbug, and owes his reputation to his imposing mane, for he will run away like a whipped cur, under circumstances in which a tiger will attack and kill."

MECHANICAL PROGRESS.

The Mechanical Age.

The London Times, criticising Lord Derby's Manchester speech, says:

However quick other countries may have been to develop the great mechanical discovery of the century, it is to England that those discoveries are mainly due; and our riches have been derived as much from the genius and patient intelligence of men like Stephenson and Faraday, as from our stores of coal and iron. But until recently manufactures and machinery were regarded very much as outlying provinces of human energy, which might be left to take care of themselves. They brought wealth to the country and fortunes to individuals, but they were regarded as no more a matter of general concern than any other trade. They are now recognized as a kind of public care; and even in his capacity of Foreign Secretary, Lord Derby was invited at Manchester to treat them as of primary importance.

Without going the length of Dr. Playfair the other day, and treating the natural sciences as almost a substitute for all human culture, it is evident that, as a matter of fact, all culture is being brought to bear upon them, and that they are absorbing energy and attracting thought in every sphere of life. In view of this remarkable revolution of thought one is a little provoked by the very matter-of-fact reasons which are usually alleged in explanation of it, and Lord Derby, in the greater part of his Manchester speech, was too true to his habitual caution in contenting himself with reiterating them. Labor, he says, is dear, and is becoming dearer; and it is consequently more and more necessary to invent labor-saving machinery. Similarly, at Leeds, the other day, even the apostles of science could find little more to tell us than that other nations are threatening to undersell us, and that we need all scientific appliances to hold our own.

All this is, no doubt, true, but the reality is too vast and broad to be adequately represented by such statements of the case. To say that we must invent better machinery because labor is dear, however accurate, is nevertheless something of a reversal of the order of facts. What has made labor dear in England? Above all, the invention of machinery. A machine is only matter animated by intelligence; and it is not merely because the wants of men have grown more numerous, but because their intellects have grown more active, that they have at length reached a stage of their development at which they are concentrating their energies on asserting the dominion of intelligence over Nature. It is this which is implied when we call the present a mechanical age.

THE USE OF BELTS.—A correspondent of the *Scientific American* says: "After many years' experience with belts of all kinds, I have learned that it will require the most power with the short, tight belt, especially if the pulley receiving the power to be much smaller than the one giving it. With the tightener there is a greater length of belt brought in contact with the pulley, consequently the belt can be much looser, and thereby lessen the friction upon the bearings. The tightener should be only heavy enough to take up the slack of the belt, which should be quite loose when relieved of the weight of the tightener, which should always be close to the pulley receiving the power. If the power is carried horizontally the long and loose belt will have a similar effect, as the slack of the belt will always be found on the side of the belt going from the giving to the receiving pulley, which will, if it be the top side, act so as to bring a much greater length of belt in contact with the pulley than in the case of the short, tight belt."

A PERPETUAL CLOCK RUN BY ELECTRICITY.—We have heretofore made mention of the perpetual clock, the invention of Mr. E. Clark, of this city, and spoken of his having applied for a patent. This patent has been granted, and Mr. Clark is turning out these time-pieces as fast as he can, but the demand is far greater than he is at present able to supply with the

facilities now at his command. These clocks are run by electricity, and consequently the trouble of winding up is obviated, the machinery running until it wears out. We noticed one the other day that had been running steadily since April, although the works had not been boxed in, the dust not having the effect of causing the slightest variation.—*Paris (Ky.) Kentuckian*.

Phosphor Bronze.

Phosphor bronze, which has recently been introduced with some éclat as an alloy of copper and bronze, proves not to be an alloy, but a true chemical combination of copper with phosphorus, or a phosphide of copper in definite proportions. The union of the two may be through the cold or the hot process, the cold sufficing for certain applications, being preferable indeed to combinations produced by heat. By the hot process the introduction of simple bodies other than the metals or metalloids is prevented. The copper used in the process must be commercially pure. Of the three kinds of phosphorus the operator may take his choice; the ordinary, the amorphous, and the earthy biphosphates. The amorphous is the most expensive, and is also the best. According to Delatol, the percentage of phosphorus varies from two to four, between which there may be an infinity of degrees, although for industrial purposes five varieties meet all the requirements. These are formed with two per cent. of phosphorus, two and a half per cent., three, three and a half and four per cent. Above four phosphor bronze is useless, but between three and four per cent. the material is claimed to be superior to any other metal or alloy. The price of phosphor bronze, unworked, should not exceed that of copper more than ten per cent.

With regard to the patents which have been taken out for the manufacture, it may be remarked that phosphor bronze and its uses as a compound dates far anterior to both the American and European patents. Both the cold and the hot phosphorization of copper was known and well described 25 years ago.

Overman, in his *Metallurgy*, New York edition of 1822, page 638, describes hot phosphorization in the following words: "Phosphorus renders copper very hard, brittle, fusible and oxidizable." A very little of this substance melted together with copper causes it to be very hard, similar to steel. Here is all that is known of this compound today. Cold phosphorization is described in the following: "Clean copper, held in the vapors of phosphorus, is successfully hardened." Years ago in our metallurgical practice, says *Mines, Metals and Arts*, we made phosphides of copper, lead and tin, and arseno-phosphides of copper and antimony, both by melting the metals, and also from the ores.

The author cited above, says, (page 430) "Phosphorus combines readily with most of the metals, and adheres tenaciously to them."

We may reasonably expect phosphorus in any metal which is smelted in the presence of phosphoric acid and carbon and hydrogen. Therefore the presence of bones, or bone ashes, in an ore or in a slag, will cause the metal to contain phosphorus. The best means for forming a phosphuret, is to heat a phosphate in the presence of carbon. Phosphorus is more easily oxidized than sulphur, and combines in this condition readily with the alkaline earths. We may, therefore, by these means, remove phosphorus. It also causes metals to be very fusible, more so than any other substance, and thus disposes them to be brittle when cold."

Foundry Charcoal.

The part which the charcoal plays in the molds is to give porosity and facilitate the escape of the gases and steam caused by the molten metal. There are three sorts in use in French foundries, known as mineral charcoal, vegetable charcoal, and stove charcoal. The first of these is made from coal finely pulverized, and is mixed with the sand used for casting pieces of small dimensions and little thickness; these are called green sand molds. But all sorts of coal are not equally good for the purpose; some kinds give a white appearance to cast iron, and produce on the surface, and chiefly at the extremities of the castings, rough spots which the file will not touch, and which have the appearance of having been run at too low a heat. M. Melifert has tried many kinds, and finds that *gras* or bituminous coal is the best, and says that, when used in small quantities and finely sifted, its action is perfect, and it gives to the casting that bluish luster which is highly esteemed.

The vegetable charcoal is made from carefully selected wood, burned in a special manner. The principal quality demanded in it is that it shall not take fire, and it is used principally for powdering the surface of the mold, so as to prevent the contact of the molten metal with the green sand. It is reduced to such impalpable powder that the spatula used for spreading it in the mold gives it a surface almost as brilliant as glass; it is called *gras*, or fat charcoal, a quality derived from the mode of burning, and it will neither roll before the trowel or spatula nor stick to it.

Stove black is used for the same purpose in the case of large castings, as the other materials will not bear excessive heat. This is simply mixed with water and applied rather thinly. A thick coating is not considered good.

The Mining Share Market.

The present week opened with a market falling and at many points pretty thorough demoralized. The disaster to the Savage mine was used as a means to force down everything on the Comstock. The weather, too, had a dampening effect on holders of stock, and for several days the bears had it their own way.

A Stupendous Work.

The international committee on the construction of the submarine tunnel between France and England having reported the entire feasibility of the project, it is probable that the work of tunnelling under the Straits of Dover will be commenced at once, and pushed forward vigorously to completion.

Meetings and Elections.

Chester Flat Blue Gravel M. Co.—Feb. 8: Trustees, C. B. Pond, (President), L. Vesin, H. Stiel, H. Kozminsky, Chas. Waldeyer, (Superintendent), O. H. Bogart, (Secretary).

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

THE AMERICAN FLINT MINE.—*Dispatch*, Feb. 5: Among the many other important mining enterprises that are being carried on in our county, the American Flint mine, located near Fiddletown, deserves special mention, as it is destined to be one of the best paying mines of the kind in the county. The work is being prosecuted under the supervision of Col. W. W. Swindley, a man of undying energy, who has now 15 men employed in laying 60 yards of 15 inch pipe to convey water to the main bank of gravel, which is from 20 to 100 feet in depth, all of which prospects exceedingly well. This will afford an supply of from 500 to 1,000 inches of water, which, at a pressure of 240 feet, will enable them to wash out an immense quantity of gravel each day, especially as the modern appliances for hydraulic mining, including two "little giants," are to be used. The gravel, after being washed out of the main bank, will be run through a flume three-quarters of a mile in length, which will ensure a close saving of all the precious metal. The new pipe will be in position ready for work in a few days, when the owners of the mine confidently expect to reap a rich golden harvest, as enough gold has been taken out during the past few weeks to pay the expenses of the company, by simply piling the surface dirt in the range of the pipe already laid.

ITEMS.—*Ledger*, Feb. 5: The Downs hydraulic claim, situated near Humming Hill, about a mile above Sutter Creek, is in full blast. They have recently shifted the hydraulic to the west end of the claim, which is a much more desirable position than where it was previously located.

The Kennedy mine has resumed pumping operations. It is determined to keep the water from rising above the 400-ft level. Several teams are engaged in hauling water to the works, charging \$7.50 per cord.

The Amador Consolidated is again yielding rock from the upper levels. The ore is of high grade, and resembles one of the good times of yore. The air is still a long way from being good. The holding of water proceeds rapidly.

Sonoma has recently sold a gravel claim near Volcano to San Francisco capitalists for \$7,000. The claim embraces some 80 acres, and the gravel varies from six to 25 feet deep.

BUTTE.

GOOD PROSPECTS.—*Record*, Feb. 5: These who have had faith in the Butte creek mines for the past 25 years are about to see their dream realized, if we may judge from what has transpired lately. Within the past few weeks various parties from Chico have taken advantage of the dull times, produced by a rainy winter, to try their hands at prospecting the Butte creek mines in the vicinity of Centerville, Diamondville and Helltown. We saw on Tuesday a very pretty quantity of dust at the Bank of Butte County to the amount of about \$1,500, that parties had brought down with them as they came home to spend the Sabbath with their families. These familiar with the mines of that vicinity are confident that it only requires a supply of water to be brought in high enough to work the gravel banks in order to open a vast extent of good paying mines. The immediate bed of the creek has been worked over and over again, and it is the high banks that are now attracting attention. In many places these can be worked to a limited extent by the winter supply of water. It is by this that the present showing of dust has been made, and it seems probable that the locality immediately famous for the richness of the bed and immediate banks of Butte creek is to be more than repaid by the discovery of vast deposits of paying earth in the adjacent hill and mountains. Why gold should not be found in the hills above "the Forks" we do not clearly understand, for Bull creek is a tributary of Butte creek, much higher up, and has long afforded very rich mining. It may be that the chain of gold paying deposits is broken, but if so it is in the hills somewhere in that vicinity. It is also known that Gravel Range, a somewhat famous locality, still higher up, is rich in mineral deposits, and there is no good reason why paying mines of great extent should not be found. If so, the water to work them will be found in the tributaries to Butte creek.

CALAVERAS.

THE GWIN MINE.—*Chronicle*, Feb. 5: The 1100-ft level is progressing finely, having already been driven 45 ft. The ledge shows four ft in thickness, and is improving in quality of ore. One small battery is engaged in crushing.

EL DORADO.

DITCH ENLARGED.—*Mountain Democrat*, Feb. 5: The enlargement of the South Fork ditch, from Smith's flat to the reservoirs south of town, is now an accomplished fact. The enlargement has been made for the purpose of conveying the water brought down from the main trunk, through the lower ditch, to the company's mines in Conch hollow. It measures six ft in width on bottom, ten feet on top, and will carry over four ft in depth of water. All the old ditches have been torn out and replaced by larger and more substantial work. The aqueduct at the head of Cedar ravine has given place to an inverted siphon of 26-inch wrought-iron pipe, which passes under the old ditch, and the Waberditch, and has a pressure of about 40 ft between inlet and outlet.

ITEMS.—The St. Louis mine, Col. O. P. Johnson, superintendent, is still at work bringing up the golden ore and promises to take rank among the first mines in the State. The ore in this mine has always been of a high grade. We understand that reduction works will be started in the spring. The Partridge mines are running to full capacity, and successfully. Robinson's mine is expected to start up soon and renew its golden current. The Oregon mine is also being prospected with great results. The opening of the spring will give movement to all our mines, hydraulic, gravel and quartz.

INYO.

THE DEFANEO.—*Oso News*, February 3: Last week in our report of this mine we spoke of a "bonanza" having been struck in the middle ledge above the first level, north of the cross-cut, which gave every indication of being very extensive. Since that time they have been cross-cutting this deposit to ascertain its extent, and at the present showing the cross-cut has been run a distance of 40 feet through a splendid body of ore, and the ore still holds out. At the south chimney, on the second level, drifts have been run from both winzes into this chimney, through solid ore, and they struck about 50 feet of making the connection, which will, if the ore continues, make the bonanza 80 or 90 feet in length, its width not yet having been determined. In the last two or three days the north chimney has, for the first time on the second level, been tapped by a drift, and from this point the very best of ore is being taken. It is of high grade in silver and contains 55 per cent, in lead. This is a wonderful mine, and in all points where exploration have been made more than meets the expectations of its owners.

BIENELL AND STONEWALL.—From C. W. Honaker, who is superintending the work, we learn the following in regard to these mines: A contract has been let on the Biennell—which is situated about one mile east of Darwin and near the Keystone—to sink on the ledge ten feet, and as much further as may be necessary, to ascertain the value of the property. The croppings are

from 4 to 30 feet in width, with all the external indications of the ledge going down to a great depth. It is believed that both mines will turn out to be good.

KATIE PEASE.—This mine situated about eight miles from Darwin in the northern end of the Argus range, near Darwin canon. Work was begun on the 29th ult. The ledge, which crops out on a bluff, was only six inches in width at the start. Some 20 feet below this bluff a cut was run in about seven feet, when the ledge was encountered, and at that depth the ore vein is 19 inches in thickness. The walls are well defined and are nine feet apart, the ore vein increasing in width as sinking progresses. The ore is of the free milling character. A contract has been let for sinking the mine on the ledge, and at that depth it is confidently believed by Mr. Kaufman, one of the owners, that a strong vein will be developed.

COGO CONSOLIDATED.—We have little to report in regard to the Bolla Union this week, as it is the desire to concentrate the work upon the double compartment shaft, which is being pushed as rapidly as possible. From the other workings of the mine more than sufficient quantities of wood ore have been and are being extracted to supply the furnace.

KERN.

A FLURY.—*Courier*, Feb. 5: A little flurry of excitement was caused a few days ago by the report that rich ore had been discovered near the town of Flury, about 14 miles from town. A number of citizens started out on Thursday morning to prospect the new find, and we await their return to learn the result. Persons who are familiar with the locality, however, are not at all sanguine of anything being found that will pay. The creek has, it is said, been prospected thoroughly year ago, and nothing was ever found to justify the claim. There are spots that will pay small wages, but most of it is almost entirely barren.

A CONTRAVENTURE.—Reports of the marvellous richness of the Bunnell mine near Kernville continue to accumulate, but the biggest thing they have on hand now is an adverse claim and a prospective expensive lawsuit. We have been informed that the mine was jumped by Morley last week. There are spots that will pay well with shotguns and other playthings. It is impossible for us to attempt to give the merits of the controversy.

MARIPOSA.

NEW PLACER DISCOVERED.—*Gazette*, Feb. 5: We have received the gratifying intelligence that the prospect of a new field of placer mining has been found in the southern portion of this county, near Hayfer's ranch. Our informant says that as high as \$20 a day was picked up, one place of the value of \$6. Quite a number of miners are already upon the spot, and we expect a host of good results from this new mining section.

PLACER.

THE MINING SITUATION.—*Forum*, Feb. 3: The severe snow storm which has been raging for the last fortnight had the effect of almost entirely suspending outside operations. All the claims in this vicinity were obliged to cease working excepting the Pacific, the banks of which, being composed of fine top gravel, are easily piped away. The various claims which require a derrick or hand labor to remove the rocks have been idly waiting for the storm to abate. At Gold Run the Judd and Cedar claims, which are both opening through bed-rock tunnels having only fine gravel to run, have been kept busy washing excepting a few days they were out of cleaning up in their tunnels. The tunnels and inclines which are being run in the bedrock here have not been affected, work on them having been continued with usual vigor. The water supply (owing to the snow and ice above), has been materially reduced, none of the ditches carrying half of their capacity.

TRINITY.

A VISIT TO THE ALTOONA MINE.—Correspondence of the *Journal*, Feb. 5: Passing Mr. Foley's, we came in full view of the Altoona mine and works. In company with Mr. Greenman, the superintendent, I went to the retorts—five in number—recently constructed and to all outside appearances working well, with a good flow of mercury and several flasks filled ready for market. The retorts are of the best construction, and are made of a high grade, from its blood-like appearance. The retorts and buildings look clean and neat, and show some mechanical skill in erection. Going into the mine I find that usual activity which indicates a paying property. Here we see the ore extracted from the vein in several places and delivered to the puddling and rolling places, preparatory to going to the retorts as 25 to 40 per cent, ore.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, Feb. 3: Daily yield, 650 tons of ore. There is no change in the rich character of the ore extracted or the favorable appearance of the ore breasts. The mills on the Carson river have been kept busy with ice but are now all running to their full working capacity. The shipments of bullion up to last evening amounted to \$1,805,000, and can be easily increased to \$2,000,000 by the 6th of the month if the company so desire, that being the date or time for declaring the usual dividend. The California mill is running splendidly, crushing ore from the mine, and will add greatly to its already enormous production. Sinking the C. & C. shaft is going steadily forward and will soon reach the 1300-ft level, at which point it will connect with the east drift on the 1500-ft level, now being run for that purpose. That drift being designed as a large working gallery is being pushed to completion as rapidly as possible, and is being timbered in the most thorough manner possible.

CALIFORNIA.—Sinking the C. & C. shaft is making the drift on the 1500-ft level, and is now down 1033 feet; the flow of water is quite strong, but is easily handled by the pumps. The north drift on the 1500-ft level has been connected with the bottom of winze No. 5 in the east cross-cut from the north drift on the 1500 ft level. This drift is now being continued north of the winze, the face still in rich ore.

OLD.—126 tons of ore. This ore is mostly taken from the 1500-ft level. The ore breasts are showing splendidly, and promise a good yield for a long time to come. Repairing the damage done by the water on the 1600-ft level, and in the east shaft below the 1465-ft level, is making steady and favorable progress. The foundation for a second air-compressor, also for a second engine, and for a second engine driving the saws and other machinery in the carpenter shop, is about completed. Both the compressor and the engine will stand in the main building of the works, the compressor on the south and the engine on the north side. Both will be in operation in three or four days. The new assay office is nearly completed, and will be in full operation in a very few days. The west shaft is now being run down to the 1500-ft level, and the shipment of ore to the Empire State mill was commenced last Monday. This mill will be started up to-day. Workmen are engaged in moving the temporary business office, preparatory to the erection on its site of a permanent and more commodious building. The new compartment of the shaft is fast approaching completion, the men employed in its excavation being engaged at no less than seven different points.

CROWN POINT.—Daily yield, 350 tons of ore. The ore is low grade and little more than pays for the cost of extracting and milling. Sinking the south winze No. 2 below the 1500-ft level is making excellent headway. This winze is being run to connect with the south drift on the 1600-ft level for air purposes, and is now down 55 feet. During the fore part of the week the south drift on the 1000-ft level, at a point 180 ft south of the Belcher line, encountered ore giving some excellent assays. The drift has penetrated into this ore belt about 15 feet, but has not yet gone far enough to determine its value. The main east drift on the 1700-ft level is being pushed steadily ahead through the ore

vein, the flow of water in the face being so strong that fears are again entertained that the work will have to be stopped until the flow subsides, on account of the pumps not being able to handle it. The main south drift on the 1700-ft level is steadily advancing to the southward, the face in good working ground.

SAYRE.—During the first part of the week the debris which had dammed the water flowing from the north drift on the 3200-ft level was removed, with the expectation that the pumps would be perfectly able to handle all the water that might flow from the drift. Contrary to all expectations, however, the water poured in until the pumps could no longer control it, and not only the incline but the 2300-ft level was completely flooded. The water continued to rise until the 2300-ft level of the Hale & Norcross was also flooded, and all work stopped in both mines. The pumps are running up to their full capacity, belasting about 20,000 gallons of water per hour. Large tanks are also being placed at work in the incline, and every effort is being made to reduce the flow of water as rapidly as possible.

BEACON.—Daily yield, 400 tons of ore. The ore here is of high grade, and it is expected will reach the 1500-ft level. The yield of the mills will not be so large for January as in December, owing to the clogging of the mills on the Carson river with ice, so that they could not crush up to the usual standard. This has caused an accumulation of some 3,000 tons of ore at the mills during the latter part of the month. The excavations for the new pump pit, and its expected will reach the 1500-ft level. The shaft is completed down to the 1500-ft level, and is now being continued on down to the 1600. A strong flow of water has driven the men out of the 1600-ft level and stopped all work in that portion of the mine.

SILVER MOUNTAIN.—Sinking the new shaft is going steadily forward, the bottom in good blasting ground. It is now down 100 ft, and it is expected will reach the 1500-ft level early in the next month. Both the north and south drifts at the 1250-ft level of the mine are steadily advancing, with no important changes to note. The south drift on the 1000-ft level is going rapidly forward, the rock in the face working quite tough and hard.

EDDY BRYAN.—The shaft is down 63 ft below the 500-ft level, the bottom in good working ground. The north drift on the 380-ft level is showing some very handsome quartz and ore. The south drift on the same level is steadily advancing, the face in quartz, with spots of good ore. Cross-cut No. 6, on the 250-ft level is showing a steady improvement. This drift has about 25 feet yet to run to reach a point under the ore body opened on the 170-ft level. On the 170-ft level, cross-cut No. 1 is steadily advancing, the face in excellent ore.

BULLION.—The northeast drift on the 2000-ft level is steadily advancing, the face still in quartz and porphyry mixed. No change in the operations on the 1700-ft level. The upraise from the 1700-ft level, to connect with the bottom of the main incline, is making good progress. Sinking the main incline is steadily progressing at the rate of about four feet per day. A waste and ore chute is being put in on the 800-ft level.

KNICKERBOCKER.—The heavy flow of water which this company has had to contend with for so long a time is at last completely mastered, and the shaft entirely cleared to show the 400-ft level. At the present rate it is expected that the shaft will be entirely drained, ready for sinking, in a very short time.

DAYTON.—Sinking the main shaft is pushed vigorously ahead, the bottom in good sinking ground. It is now down 28 ft below the 600-ft level.

AMAZON & GLASGOW.—The north and south drifts, on the third station level, are steadily advancing, the face of the south drift showing some fine sulphure ore. The north drift is also evidently approaching the ore body, the quartz in the face carrying more sulphurets and the ore is getting in increasing. The prospects of the mine are quite growing brighter.

OVERMAN.—Sinking the shaft is making slow progress, owing to the strong flow of water at the bottom. The main west drift on the 1100-ft level is steadily driven forward without change of interest. The pump-bath at the 700-ft level is nearly completed.

SUCCESS.—A very important strike of ore was made in the bottom of the shaft on the 1300-ft level, the surface, during the fore part of the week. The ore is of the white Comstock formation, and average assays give \$40 per ton, mostly silver. The extent of the ore has not yet been determined in any direction whatever, a breakage of the pumping machinery allowing the water to rise in the shaft to such an extent as to stop all work in the bottom. The damage will, however, be repaired in a very short time, and the sinking resumed.

ROSAUTH.—The main south drift on the 380-ft level is steadily advancing, the face in solid quartz. A cross-cut has been run from this drift a distance of 40 ft, the entire length of which is in quartz and ore of a very encouraging character. The main south drift on the 500-ft level is in 83 ft. The north drift on the same level is in a distance of 35 ft.

NORTH COAST VIRGINIA.—The 630-ft station and water tank is nearly completed. It is confidently expected that this tank will take up very nearly if not all the water in the bottom of the shaft, leaving it almost perfectly dry.

BUCKEYE.—Our report of last week had hardly gone to press before the news was brought that the fly-wheel of the driving engine had broken to pieces, greatly injuring the foundations of the machinery. This break has necessitated the shutting down of the engine, and the incline, flooding all the lower portion of the mine. The damages will be repaired and the water extracted at the very earliest moment possible.

JULIA.—The shaft is down 1650 ft, the bottom in excellent working ground. This is the new deepest perpendicular shaft on the Comstock lode. The main south drift is now down 1600 ft, and the sinking resumed, the face in ledge material of a very favorable character. The face of the south drift on this level is in fine quartz and ore. The main southwest drift on the 1400-ft level is in a distance of 782 feet, the face in soft ledge material of a very encouraging character.

UTAH.—The new pumping machinery is working with the utmost perfection, and the water has been drained from the shaft to a point 30 ft below the 400-ft level. The shaft is again in good repair to that depth. The station at the 400-ft level is badly caved, and a strong force of men are at work repairing the damage.

ORIGINAL GOLD HILL.—The ore dump being full, and the roads too bad to allow of hauling, ore extraction is temporarily suspended. The development of the mine goes ahead as usual.

JUSTICE.—South drift at the 1000-ft level continues in easy working vein material, with considerable water. Drift south at the 800-ft level in porphyry, clay and streaks of quartz which give low assays. The ore-stopes and breasts of the 600 and 400-ft levels are showing well.

PROCTOR.—Drift north has been started, following the west wall of the back ledge. It is running in very favorable vein matter, composed of porphyry, clay, and quartz which gives low assays.

UNION CONSOLIDATED.—The north and south winzes, on the 1300-ft level, are still being pushed downward, the bottom of both being in quartz and low grade ore. The cross-cut from the north drift, on the upper tunnel level, is steadily advancing, the face in a heavy body of tough clay.

IMPERIAL EMPIRE.—Daily yield, 30 tons of ore. The ore breasts are looking well, but that amount is all that the teams can haul to the mill. The north drift on the 2000-ft level is steadily advancing, the face in very favorable quartz and ore. The south drift is also advancing, the face in quartz and low grade ore. The bottom of the winze below the main tunnel is also looking well.

LADY WASHINGTON.—The 830 station and pump tank at that point are completed, the plunger is lowered

into position, and the pump column and rods are being lowered.

CHOLLAR-POTOSI.—The south drifts on the 1250 and 1350-ft levels are steadily advancing, without change of value to report. Daily yield of ore, 60 tons.

ROCK ISLAND.—Sinking the main shaft is making good headway, the bottom in good blasting ground. Cross-cutting a ledge on the 350-ft level is going steadily forward.

NEW YORK CONSOLIDATED.—The east and west drifts on the 800-ft level are steadily advancing, without change or interruption. This west drift is showing some very favorable streaks of quartz.

MEXICAN.—Sinking the winze below the 1465-ft level is making excellent progress, the bottom still in very favorable looking quartz and low-grade ore.

SULLIVAN.—The east cross-cut from the south drift has passed through the hard streak of porphyry mentioned in last week's report, and is now into the regular white ledge matter again. This is soft and easily worked and gives a better showing of quartz streaks than has yet been developed at this level, encouraging the idea that the eastern section of the mine will be rich in quartz streaks all carry more or less metal, and will assay from \$5 to ten in the hundred. They are simply little off-shoots, branches or feeders to a main ore vein which will be found some day.

SILVER HILL.—This new incline pump is in place, and works well. The main incline is down 70 feet in the new shaft, and is in the bottom of the north working well, and the Berlich drifts forcing the sinking ahead at a very rapid rate. The flow of water from the face of the east drift, at the fourth station level is still strong, but seems to be again gradually lessening.

HALE & NORCROSS.—The strong and steady flow of water from the north drift of the 2200-ft level of the Savage has raised in the Savage incline until running is now down 100 ft, and it is expected will reach the 1500-ft level of the Hale & Norcross, causing a complete suspension of work on the lower levels, until the water is checked in the Savage.

YELLOW JACKET.—The two east cross-cuts from the bottom of the north and south winzes on the 1940-ft level are steadily advancing, the face of each being in favorable working ground. No change is expected in any of the prospects or operations on the 1740-ft level or the north drift from the bottom of the north winze on the 1940-ft level.

BEST AND BELCHER.—Rotimbering the double winze below the 1500-ft level is finished to within about 30 feet of the bottom. The work is going ahead as fast as the pressure of the ground will permit. The water still stands to the depth of three or four feet in the north drift from the Gould & Curry shaft on the 1700-ft level.

CALEDONIA.—Sinking the main shaft has been greatly retarded during the past week by the heavy flow of water at the bottom. The large sinking pump has been again put at work in the bottom, and everything is now going forward as usual.

CONOVER.—The repairs to the machinery are not yet completed, but will be in a very few days, when drifting and sinking the shaft will be resumed.

GOULD & CURRY.—Repairing the main shaft is progressing very favorably. Otherwise there is no change of consequence in any other portion of the mine.

MINT.—The repairs and improvements in the shaft are almost completed, ready to resume sinking the main shaft.

SILVER CITY.—The raise mentioned in last week's report is now up 35 feet above the car track of the main adit level, and all the way in ore of high grade, especially at the top, where it is about six feet in width. Superintendent Henry is now breasting out both north and south, from the top of the raise, using it as an ore shaft. It is now far above the first one, and is not known at present, but he wishes to connect with the main ore stope south as soon as practicable, and also open out the vein northward. The ore developed at this point is among the best ever found in the mine.

BALTIMORE AND AMERICAN FLAT.—The main incline is being steadily crowded downward, the rock in the bottom blasting out finely. The incline pumping machinery is all in place, ready to start up.

NORTH CAREY.—Very good progress continues to be made in both sinking the main shaft and running the north drift. Good prospects at both points.

FLORIDA.—The grading and preparation for the erection of the first-class new hoisting machinery goes ahead at a very lively rate.

NEVADA.—Face of main north drift still advancing in porphyry and clay and streaks of low grade ore.

SURCO.—The main west tunnel is steadily advancing. The flow of water is light.

ALTA.—Sinking the main shaft is going steadily ahead. Otherwise nothing new.

PROSPECT.—Both shaft and drift driving ahead as usual, and promising well.

ROUGH AND READY.—Good progress made in sinking the new working shaft.

ELY DISTRICT.

RAYMOND & ELY MINE.—*Pioche Record*, Jan. 30: During the past week the pump has done some good work, keeping the main shaft dry. The working parties have been busily employed in cutting a tank station, sinking progressing but slowly in consequence. The extra pump rods have been placed in position and as soon as the tank is completed sinking will be proceeded with.

The upper levels are in a good state of being extracted, especially from the tenth level, from which place fine ore is being taken out. The shipments for the past week show an increase with plenty more in sight. The ore worked at the mill shows a very fair average and is easily worked. The present appearance of the mine is even better than it has been for the past eighteen months.

ALPS.—Since our last report no new development has been made in this mine. The gold-quartz ledge continues as before reported, a fair amount of ore being taken from it every day. This ore is held in reserve at present. In the balance of the mine work continues as usual. The upper portion from 15 to 20 tons of ore is daily hoisted to the surface. On the lowest level work is continued vigorously as possible, the rock being very hard and progress necessarily slow. The superintendent judges that they will have to go about 70 ft further before the ledge will be struck. The ore extracted daily is increasing in quantity and the appearance of the mine justifies what its owners have said.

ANASO VALLEY.—There is no change to report in the working of this mine, the work being continued as usual to the 1200-ft level, running the north cross-cut, which is being advanced rapidly. Chloride contractors are shipping fair amounts of ore daily to the Newark mill for reduction.

EUREKA DISTRICT.

THE JACKSON.—*Eureka Sentinel*, Feb. 6: Work is being vigorously prosecuted at the Jackson mine. Since work was resumed there the shaft has been sunk upwards, or rather downwards, 60 ft, and has now attained a depth of 350 ft from the surface. It is now a species of iron rock, which is considered a better indication of the proximity of ore than the slate in which it was running, until the last 20 or 30 ft. A drift is being run under the old ore body from the 300-ft level. In this drift a quantity of tolerably fine ore has already been struck, and any blast or stroke of the pick is liable to develop a body of ore, which has given the mine such a reputation a few years ago.

WARD DISTRICT.

THE ELKO.—*White Pine News*, Feb. 6: The parties who are working the lower end of the ledge of the Elko mine are taking out large quantities of high grade smelting ore, and are making a very good thing of their lease. There are a score of good properties lying idle in the district that could be made to pay just as well as Elko, and which could be had by making the proper application.

(Continued on Page 108.)

Value of Mining Property in Nevada County.

The Nevada Transcript has been favored by John T. Morgan with the following statistics from the assessor's office, which will be of interest:

The gross assessment of Nevada county for the year 1875 was \$7,893,547, divided as follows—Nevada township, \$1,342,215; Grass Valley township, \$1,984,830; Rough and Ready township, \$434,955; Bridgeport township, \$1,249,510; Bloomfield township, \$501,150; Washington township, \$180,835; Little York township, \$334,135; Eureka township, \$570,185; Meadow Lake township, \$1,295,732.

The following are the water and gravel claims of the county, assessed at \$10,000 and over: Milton mining and water company, \$381,660; Eureka Lake and Yuba canal company, consolidated, \$367,425; North Bloomfield gravel mining company, \$235,500; South Yuba canal company, \$167,600; Excelsior canal company, \$100,000; American mining company, \$80,000; Omega water and mining company, \$60,000; Birdseye Creek gold mining company, \$59,500; W. H. Dnyra mining claims, \$58,680; Little York water and mining company, \$53,150; Jacobs & Sargent water and mining claims, \$40,000; Sweetland Creek gravel mining limited company, \$40,000; Yuba Tunnel gravel mining company, \$30,000; Badger Hill and Cherokee G. M. company, \$30,000; Manzanita mining company, near Nevada City, \$28,500; English gravel mining company, \$25,000; Blue Tent Consolidated hydraulic G. M. company, limited, \$25,000; Liberty Hill mining company, \$18,100; Trust and Hope gravel mine, \$14,000; Smith, Alexander & Bell gravel claims, \$12,000; Blue Bank gravel mining company, \$10,000; total assessed value of all mining claims in the county in 1875, \$1,394,335; value of improvements on mining claims, \$457,815; total assessed value of mining districts, \$960,805; assessed valuation other than town lots, \$546,015; improvements on the same where assessed to the same owners, \$333,587; assessed value of town lots, \$232,230; improvements on the same where assessed to the same owner, \$800,040; improvements on all property assessed to others than the owners of land, \$67,206; total value of all personal property as assessed in 1875, \$2,572,047. Assessed value of telegraph lines, \$9,962; toll roads, \$37,850; railroads, \$358,360.

The following is the assessed value of the leading quartz mines of the county in 1875: Idaho mining company, \$310,000; Empire mining company, \$60,000; Eureka gold mining company, \$51,000; Providence gold and silver mining company, \$30,000; North Star gold mining company, \$25,000; Marietta mine, \$20,000; Nevada gold quartz mill and mining company, \$20,000; New York Hill mining company, \$20,000; California Consolidated mining company, \$15,000; Pittsburg mining company, \$10,000.

A Model Assay Office.

The destruction of the old assay office by fire and the steady increase of the monthly yield of the Consolidated Virginia mine, with the prospect in a very short time of the California doubling the amount of assaying to be done end the bullion to be handled, has caused Messrs. Mackay & Fair to erect an assay office and bullion reduction works commensurate in fitness and size with the immensity of their business, and which, without doubt, is superior to any private assay office on the globe. A peep at the inside and its appointments may not be uninteresting to our readers. The office is situated on the south side and immediately adjoining the hoisting works of the Consolidated Virginia. The building faces on F street, is 45 feet in width, 85 feet in length and two stories in height. The lower story is 12 feet in height, and contains the assaying and smelting departments. The upper story will be divided into offices for the superintendent of the mines and the chief secretary and his assistants. Running the whole length of the building on the front is a platform just the height of a wagon bed, greatly facilitating the loading and unloading of bullion. Built through the center on the ground floor, running the entire length of the building, and back again, is a double line, with a chamber two and a half by five feet in size, and a total length of 170 feet before reaching the south end of the building, where it ends in a huge brick smoke stack, 40 feet in height, on top of which is again placed an iron stack 50 feet in height. This fine is sheeted in the bottom with iron, and is built on the best improved plan for saving the silver which is constantly being carried off by the fumes and vapors while smelting. Extending across the building 30 feet from the north end is a hall 10 feet in width, which is to be furnished with a car and track for conveying the bullion to and from the assay and smelting rooms. The first room in the northeast corner is 12x15 feet in size, and will be used for the assay weigh room. Adjoining this on the south is the humid assay room, 12x15 feet also. In the center of the building, on the west of these, is the clerk's office and calculating room, 12x24 feet in size. West of these, in the northwest corner, is the laboratory and cupelling room, 18x24 feet in size, from which, crossing the hall, the visitor enters the ore assay weigh room, south of and adjoining which is the ore assay furnace room. The southwest corner room is occupied as a store room for supplies and a bath room furnished with

hot and cold water. The melting room has no ceiling, the two stories being open to the roof. It is situated in the southeast corner of the building, and is 22x50 ft in size. It contains eight furnaces, built on the best improved plans, with grate bars that can be removed or adjusted in a moment, when necessary. Its capacity is estimated at 2,500 pounds of bullion, avoirdupois, at a single melt. The draft of the furnaces is strong enough to instantly snuff out a candle. The office is furnished with two ore assay, one cupelling and two muffle furnaces. The ore assay and bullion departments are kept entirely separate in all their workings. On the first floor is a huge vault for the bullion, while on the upper floor is another vault for the valuable books and papers of the superintendent and secretary. The building is furnished throughout with glass doors, so that it is well lighted in the daytime, while at night it is furnished with gas jets in every room. The assaying and smelting capacity of the entire works is estimated at from \$5,000,000 to \$6,000,000 of bullion per month.—*Gold Hill News.*

Eureka's Bullion Product in 1875.

An item has been going the rounds of the press for some time, furnished by some one at Palisade, in which the total amount of bullion, base and refined, shipped from that point during the year 1875 is given. The item does not do credit to the different mining districts, being manifestly incorrect, as the shipments alone from Eureka district are greatly in excess of the round numbers thus furnished, which includes not only this, but White Pine, Tybo, Gila and other districts. Though we are unable at present to give the exact figures for the outside districts, through the courtesy of Samuel Cooper, agent of Wells, Fargo & Co., at this place, we now present the precise amount of bullion shipped and the value thereof, from January 1st, 1875 to January 1st, 1876—the product of the mines of Eureka district alone: Base bullion, 25,143,705 pounds, valued at \$1,233,730.14.

In addition to this, the value of refined bullion shipped during the same period amounts to \$1,026,328.06; all, with the exception of two or three bars, being from the Richmond. It will thus be seen that during the past year \$5,260,058.26 in bullion were shipped; a showing that speaks for itself as to the wealth of our mines. And yet this is only a beginning. The wealth of our district is but commencing to be developed. The immense discoveries made during the last year in our leading mines has instilled new vigor in the hearts of the claim holders, prospecting is being diligently prosecuted, and before our Centennial year has passed there will be a score of such mines as the Richmond, Eureka Consolidated and K. K. to swell the wealth of the now second district of the State, but destined soon to lead the van.—*Eureka Sentinel.*

The Carson Appeal is authority for the statement that the wages of trackmen and watchmen, of whom about 50 were formerly employed by the V. & T. R. R. company, have been reduced from \$3 to \$2.50 per day, and that in consequence about half of them have quit work. It further states that, under the new deal, all Chinamen formerly employed as section hands by the company will be discharged, and their places filled by white men. The reduced rate is still fifty cents per day above what is paid to section men of the Central Pacific. As near as we can learn, no reduction has been made in the wages of the men working on the railroad this side of the scales on American Flat, with the single exception of the night watchman at the Baltic switch.

Dr. J. S. LEFFINGWELL, writing from Florence, Arizona, to a friend in San Diego, says: I write you from the richest mining region I have ever seen or heard of. Samples of virgin silver were brought from the Pinal district today, which will assay twelve ounces to the pound; 1,000 pounds of this mineral will be here in a few days, and there are four or five tons in sight at the mine. I have some very fine claims in the vicinity of the Silver King mine, not so rich as the one mentioned, but they assay into hundreds. I will give you or any desirable person a half interest in any one of them, who will furnish capital to develop the same.

Mr. HALL, president of the Fryer-Noble melting mining company, says the Nevada Transcript, has now become a permanent resident of this coast, having disposed of his business in New York so as to allow him to devote his whole time to this new enterprise. He is very enthusiastic over the prospects of the State, and says California mines as an investment are at present attracting the attention of Eastern capitalists more than ever before.

An amateur Virginia scientist has finally solved the question as to how the Comstock lode was formed, and it is so simple that we wonder nobody thought of it before. Standing above the town, he remarks: "Mount Davis (Davidson) was there; then came a corruption—hence was caused a fissure and then the Comstock was deposited by congestion."

The snow is so deep in the Little Cottonwood mining district, Utah, that all travel and transportation of ore is impossible. Snow alides occur every few hours, sweeping down forests and wrecking cabins, and occasionally burying miners so deep in the debris that a search for their bodies would be useless.

The San Francisco Microscopical Society.

The annual meeting of the society was held on Thursday evening of last week, and aside from the reading of reports, election of officers and kindred business, but little done.

Messrs. S. B. Boswell and J. Z. Davis having complied with the by-laws, were transferred from the resident to the life roll. The President, Prof. Wm. Ashburner, made a very full and carefully compiled report of the doings of the society for the past year. The Treasurer, Mr. C. G. Ewing, presented a very favorable report of the financial condition of the society, and the librarian, Mr. J. P. Moore, handed in a complete inventory of the property, library, objects and materials in the hands of the organization.

The Nominating Committee reported the names of the old board for re-election, feeling that they were the right men in the right places, which seemed to be fully concurred in by the members, for upon balloting the following gentleman were unanimously elected to serve as officers and trustees for the ensuing year, viz.: Prof. Wm. Ashburner, President; Henry C. Hyde, Vice President; Col. C. Mason Kinne, Recording Secretary; Chas. W. Banks, Corresponding Secretary, and Chas. G. Ewing, Treasurer.

After the reading of the reports, Mr. Hyde offered the following, which was unanimously adopted.

Resolved, That the thanks of this society be tendered to our worthy President for his regular attendance at our meetings, and assiduous attention to the interests of the society, as well as for his interesting and very satisfactory report of our progress during the past year; to our two Secretaries and Librarian, for the careful and laborious performance of their respective duties, and, last, though by no means least, to our Treasurer, whose indefatigable efforts are in a great measure evidenced by his report this evening.

The thanks of the society were also tendered to Dr. Harkness for his interest in, and work he had done, for the benefit of the society, after which the meeting adjourned.

The Amador Canal.

The Amador canal and mining company have just discharged a gang of men that for a month past has been at work raising the bulk-head and the heavy stone abutments at the head of the canal.

During the heavy storm at the commencement of the present rainy season, the river overflowed the head gates, filling the canal with sand and debris, thereby causing no little damage and delay, and rendering necessary these improvements as a protection against future floods. Since the completion of the canal in October, 1874, this company have expended many thousands of dollars in improvements. Two miles and a half of flume, built by the old company, three feet wide, has been widened to six feet. The large dam at New York reservoir has been raised 16 feet, and the smaller one completed. The Buena Vista ditch has been purchased, enlarged, and put in running order. This branch is 22 miles long, and is used as a "second water" ditch. Its capacity is 600 inches every 24 hours. A pipe 15 inches in diameter and 3,500 feet long has been laid from the main canal to the divide, between Sutter and Amador creeks. This pipe passes under Sutter creek and sustains a pressure of over 350 feet. The original Amador ditch, nine miles long, has been enlarged and extended a mile to the Bunker Hill mill, on Rancheria creek. The St. Mary's hydraulic claim has been fitted up for working on an extensive scale. This claim uses 800 inches of water, and is run day and night. As a crowning act, at nearly the close of the last dry season, the Blue lakes were dammed, thereby securing for the canal a never failing supply of water during the dryest seasons. These extensive improvements have more than doubled the value of the company's property. Indeed, taking into consideration the magnitude of the works, the thorough and substantial manner of their construction, together with its extensive water privileges, the Amador canal and mining company can justly claim to own the most valuable water and ditch property in California.—*Amador Ledger.*

LOOK OUT FOR MOTHER EARTH.—And now there is more trouble ahead for our planet. Mr. Andrew Wilson, who has been writing pleasantly about the "Abode of the Snow" in Asia, revives an old theory of some ancient savant that the earth will topple over one of these days and send the oceans sweeping over the continents. It seems that the earth, that is, the portion of it which is not water, somewhat resembles a huge iceberg which, becoming topheavy by the destruction of its submerged parts, thereupon indulges in a summer-sank. So, Mr. Wilson thinks, that owing to the greater preponderance of water in the southern hemisphere, the greatest accumulation of water is around the South Pole; that when the accumulation has reached a certain point, the balance of the earth must be suddenly destroyed—the center of sphericity abruptly changed from the center of gravity, and the whole earth, almost instantaneously, will turn transversely on its axis, move the great oceans, and so produce one of those grand cataclysms which have before now altered the whole face of the globe.—*Ex.*

JOHN CONNELL, a miner in the Omaha mine, Grass Valley, lost both of his eyes by an explosion last week. He is a poor man with a large family, and his fellow laborers made him up a purse of \$700, to which Mr. Dodsworth, the superintendent, added \$50.

Will the Rothschilds Gain a Monopoly of Quicksilver?

A member of the Rothschild family has lately made a tour through the mining districts of California. The circumstance has aroused the California mind to the anticipation of great investments by the Rothschilds in the gold and silver mines of the State. Yet a slight acquaintance with the principles and history of the great banking house would demonstrate the unlikelihood of its embarking capital in an undertaking like gold and silver mining, where the product is fluctuating and precarious, the value of the commodities practically inflexible, and a control of the market quite impossible.

There is, however, an investment which might well tempt the Rothschilds in California, which is recommended by their traditions and experience, and which would assure them the monopoly of a staple indispensable to practical metallurgy.

The demand for quicksilver, which is incessant and presumptuous throughout the mining countries of the globe, is met mainly by two mines—New Almaden, in California, and Almaden in Spain. For some years previous to 1869 the annual yield of this metal was computed at seven millions of pounds. To this total the works at Idria, in Austria, Carniola, in Tuscany, Hungary, Transylvania and Peru contributed about half a million, while New Idria and other minor California deposits were credited with the same quantity. Six-sevenths of the whole, or the bulk of the world's product, evenly apportioned between the American and Spanish Almaden.

In practice, the former has usually fed the markets of Europe, Siberia and India, resigning to its youthful namesake those of China and Japan, as well as all the gold and silver bearing regions of this continent which skirt the North and South Pacific. The prompt and equitable adjustment of price to the shifting conditions of consumption and production, which has hitherto been guaranteed by the competition of two independent sources of supply, would be permanently imperiled by the concentration of their stores under the control of a single will. Now, it is a fact that the mine of cinnabar at Almaden, in Spain, has long been leased by the house of Rothschild.

There is reason to think that a monopoly of quicksilver might be made the instrument of a formidable advance in the price of the commodity without entailing that shrinkage in demand which is the normal corrective of such abuses. For the treatment of those chlorides and sulphurets which constitute the richest ores of argentiferous veins as well as for those rebellious pyrites with which gold is so often found mechanically combined, the familiar process of amalgamation is the simplest, most convenient and most effective. Indeed, the mill-men of California and Nevada, the practical metallurgists of Mexico and Peru neither know nor tolerate any other.

Moreover, in many American mining districts the margin for appreciation in the cost of reduction is very large. On the Comstock lode, at all events, the value per ton of the mineral developed by recent excavations is so considerable that no conceivable increase in the expenses of amalgamation would form an item of decisive moment. It is known, for instance, that in 1874, owing to a diminished production of the California mine, caused by obstructions of a geological character, and a corresponding falling off in its Spanish rival, occasioned by political disturbances, the price of quicksilver attained to \$1.60 per pound, or almost treble the figures at which it ruled five years before. A corporation, therefore, or a banking house, which should exclusively control this metal, might impose a tax on the bullion product of Nevada whose limit could only be determined by its own foresight and discretion.

We may surmise that among the rosiest speculations which have been suggested to the representative of the Rothschilds, the astute miners and mill owners have made no reference to cinnabar. But they who have marked the policy of that house, would be little surprised to hear that a purchase of the American Almaden had complemented their Spanish investment, and secured to them a conclusive monopoly in the quicksilver markets of the world.—*N. Y. Sun.*

HAND VS. HEAD LABOR.—At a recent distribution of prizes at Greenwich, Mr. Gladstone delivered an eloquent address, in the course of which he said that one of the first results of elementary education was to produce a desire on the part of young persons or their parents to escape from the necessities of manual labor, and pass into what is called head work. Here they had before them a very important subject. There was far too much eagerness on the part of the working classes to get out of the working class into another which was not a working class. The first thing a man ought to do was to elevate his vocation. A workman ought to strive to raise the character of the work he performed, and in doing that he was doing more to raise himself and his family and class than by hurrying out of his position. Hand labor was progressively and rapidly rising, whereas head labor was falling. The ex-Premier, in conclusion, urged that what the workingman should aim at was to raise the character of the labor which he was called upon to perform.

MANY of the houses in Virginia City are protected against avalanches by V-shaped structures, intended to divide and turn aside the descending snow.

Useful Information.

Edible Birds' Nests.

Edible birds' nests are found for the most part in the Southern Archipelago. The chief region of supply is that comprising Java, Borneo, Celebes and the Sula islands. The bird which produces the nest is a little swallow, *Hirundo esculenta*. This Salangan swallow, as it is called, is slightly bigger than a blue tit; it has a brown back; but the under surface of its body, as also the extremities of the feathers in its forked tail, are white. It flies with wonderful speed and precision; and on the Java coast, where the surge breaks wildly against the precipitous and caverned walls of rock, the little birds may be seen in swarms darting hither and thither through the spray. They probably feed on mollusks and other small animals which abound on those coasts. As you watch the surface of the water rising and falling, you notice how the holes in the rock are now concealed, now open again; and the little creatures watching their opportunity, dart in and out with lightning speed. Their nests are fixed to the arched roof of those caverns.

What sort of a thing then is the edible bird's nest, that ministers to the taste of the Inxarous Chinese. It is that portion of the fabric which serves as a sort of bracket on which the nest itself (made of grass, seaweed, fibers, small leaves, etc.) is built. There are two forms of this support, one flat like an oyster shell, the other deep and spoon-shaped. It is a transparent mass, somewhat like isinglass, mother-of-pearl or white horn, and is of animal origin. It was formerly supposed that this gelatin-like mass might be prepared in the bird's crop, from seaweed and other marine plants. This, however, is a mistake. If one opens the animal's stomach about the time of building, it is found to contain insects, but no vegetable matter; moreover, in all species of the family of swifts, the crop is waiting. Dr. Bernstein has found that at that season the salivary glands under the tongue are enormously developed. On opening the bill they are seen as two large swellings, one on either side, and these chiefly supply the material in question. They secrete a viscid mucous substance, like a concentrated solution of gum arabic, which can be drawn out of the mouth in long threads, and in the air it soon dries, and is found to be the same (even microscopically) as the bracket material.

When one of the little birds wishes to begin building, it flies repeatedly against the selected spot, pressing each time a little saliva against the rock with the tip of its tongue. This it will do from ten to twenty times, moving away not more than a few yards in the intervals. It then alights, and arranges the material in semi-circular or horse-shoe form on the rock, continuing to add saliva to that already deposited, and by the motions of its body from side to side the yet soft saliva is forced out over the harder parts, producing those peculiar undulatory bands which give the nest a stratified appearance. It is thought not unlikely that part of the secretion used by the bird comes from the largely developed glands in its stomach; also, that gelatinous matters picked up in the surge are employed in the construction of its nest. The Salangan never uses the same nest more than once, and that for only a month; and after the young brood is flown the nest soon decays and falls to pieces.—*Chambers' Journal*.

EXTRACTING OIL FROM ROSES.—The process of extracting oil from roses, which is known as the costly and delightful perfume attar of roses, is very simple. It is carried on extensively near Adrianople and the Kezanlik valley, in Roumelia. Three pounds of the flowers produce but one pound of attar. The appliances are a copper kettle ending in a narrow neck, to which a condensing tube is affixed, and containing about 250 pounds of water to 25 pounds of rose leaves. The first distillation produces rose water; this distilled a second time yields an essence on which the pure oil floats. This is skimmed off in minute quantities and preserved in tight bottles for sale. An average production is 1,500 pounds in one season. The flowers are picked from April to June. Very little pure attar is to be procured, the dealers in this article, as in some others, pretending to believing the pleasing fiction that consumers would rather have the adulterated one.

THE BLUEISH GREEN BRONZES used for ornamental articles are very easily imitated. Almost any metal is first covered with a varnish made of ground tin or bronze powder rubbed up with honey in gum water. Then wash with a mixture composed of sal ammoniac half ounce, common salt, half ounce, and one ounce of spirit of hartshorn in one pint of vinegar. After applying the mixture, leave for a day or two in the sun, and then, if necessary, add a second coat. This is a good way to renovate old gas fixtures.

A MONSTER BOILER.—The largest soap boiler in the world, probably, may be seen at Babbitt's soap works, corner of West and Washington streets, New York. It is made of wrought iron, and will hold 1,200,000 pounds of soap. It was built in 1872, and is constructed of wrought iron. It extends from the ground floor of the building up through five stories, and is quite a curiosity in its line.

AGE AND OBJECT OF THE PYRAMIDS.—M. A. Dufew, member of the Egyptian Institute and of the "Society of Historic Studies of Paris," claims to have made some very valuable discoveries relative to the age and object of the four pyramids of Gizah, principally of the great pyramid, containing chronologic and scientific data for establishing the date of their construction, for determining the era of the monarchy of the Pharaohs, and the degree of knowledge displayed by the ancient Egyptians in astronomy, geodesy, hydraulics, geography, geology, and in regulating the inundations of the Nile for the benefit of their agriculture. He has written a book about it, in which he claims that the methods by which he has been led to his discoveries are entirely new. According to his view Menes ascended the throne of Egypt 5,641 years before Christ; the great pyramid was founded 4,862 years before Christ; all the pyramids were designed simply as monuments of high science, and were the work of priests of the idolatrous religion of the Pharaohs. The mystery of these awful monuments of the past has been penetrated and reported upon so often and so differently, by different students of the subject, that one cannot help feeling as though fancy has as much to do with the interpretation of the pyramids as science or judgment. M. Dufew is sharply criticised by some of his own countrymen, probably with justice.

ROMAN IRON FURNACES.—It is rather remarkable that Roman iron slags are always found on the tops of hills, and never in a valley, where water power could have been utilized to effect a draft. Hence it is inferred that the Romans never used bellows, but that they employed the natural draft of the wind in some manner. The indications are that hollows or shafts were dug out in the hill top, to which a long tunnel was driven from the side of the hill against which the prevailing wind blew. Through this open passage-way to the bottom of the furnace there would be a strong draft, which could be utilized for blower purposes. It is evident such a process must have been very inefficient, and attended with great loss of iron, which must have been left in the slag. Similar furnaces were used in Derbyshire, England, as late as the 17th century, probably handed down from the Romans.

HOW TO OIL A MILL SPINDLE.—Professor Norvel Hoge, of Greene county, Pa., suggests the following method of oiling a mill spindle, which may be of value to some of our readers. He says: "Bore a hole of suitable size diagonally through the follower, (if made of wood,) from the outside bottom corner to the inside top corner, into which insert a piece of lead or tin tube, fitting neatly, trim the upper end to fit the spindle, then prepare another similar tube that will fit nicely inside the first, provide a piston to fit the inner tube, inserting the piston into the lower end of this inner tube, fill it with oil, after which introduce it into the tube in a bush follower from the under side. To oil the spindle as occasion may require, press the piston upwards, and when the oil is exhausted, take out and refill the inner tube."

Iron is the symbol of civilization; gold represents wealth. The value of the former in the arts can be measured only by the progress of the present age. In its adaptations and employments, it has kept pace with scientific discoveries and improvements. Hence the use of iron indicates the advancement of nations. Iron is worth more to the world than all other metals combined. We could dispense with gold—it ministers largely to luxury and refinement—but iron represents the honest industry of labor. Its use is universal. There is no "California" of iron; it is found in great abundance in every nation on the earth. From this fact we discover how indispensable the Creator deemed this metal to the education and development of man.—*Ex.*

GOOD HEALTH.

Typhoid or Remittent Fever.

Messrs. Editors:—There has been a good deal of sickness in our county during the last six months. In different localities different causes have been assigned; by some the drouth of the past season has been made the scapegoat.

Among children a fever which has been misnamed "typhoid," and for which "remittent" would be a more proper designation, has caused some mortality. As cases are still occurring, I thought I would mention in your columns my own experience, which may be of use to some anxious mother, distant from able medical advice.

In the fever which attacked my own three little ones there were two or three febrile paroxysms and remissions during the 24 hours. The paroxysm at midnight was usually the worst, head hot and throbbing, body quivering and shuddering, and starting. Perhaps some slight disturbance of the brain, but not enough to constitute "typhoid" fever; drowsiness, but not sound sleep; disinclination for food, but considerable thirst. When the paroxysm had passed the body returned to nearly its normal temperature.

The treatment which acted "like a charm" on my little ones was the administering of 20

grains of cream of tartar, dissolved in a tablespoonful of boiling water, to which a little sugar was added to make it more palatable. For a drink "Imperial" was used; it is made as follows: scald a jug, put in a quarter ounce of cream of tartar, and pour thereon one quart of boiling water, adding a little lemon peel, or essence of lemon, and sugar to make it nice. The child may drink freely of this, but must be almost starved as regards solid food, until the fever has almost or quite gone.

It is most distressing to see a child's flesh waste away; one's heart aches to give it food, but while the fever is raging, giving food is merely feeding the flames, and usually the child's stomach revolts from any food proffered.

Keep the patient warmly clothed and out of "drafts" of air. If the child is "teething," lancing the gums will probably be beneficial.

Cream of tartar is both diuretic and purgative, and if the first dose produces a sufficient result, in each way, before the expiration of 24 hours, it need not be repeated; if it has not been efficacious a second dose may be tried. Take care that the medicine has not lost its virtue from long keeping.

Possibly so well known and common a drug may be discredited under its usual homely name. If so, you can call at the drug store for bi-tartrate of potash, or according to the new chemical, nomenclature, "potassic bi-tartrate" and use that as you would our old familiar friend, "cream of tartar."

It is astonishing, Messrs. Editors, how potent a few "long tailed" words are sometimes. I once heard of an old lady, who had been sitting under some pet preacher, relating her experience of his discourse, as follows: "Ah! my dear, it was a wonderful sermon; he used that blessed word 'Mesopotamia' three times." Similarly some sick folks appear to think that a prescription a yard long is more likely to suit their disease than a simple remedy.

A physician in a neighboring town, who is notable for his common sense treatment of diseases and his low charges, once told me that he had been looking over the files of old prescriptions in a drug store, and had found combinations of six or seven different drugs in one mixture. What the prescriber expected to be the action, or re-action, or mal-action, of those drugs in the miserable patient's stomach, was beyond the flight of my friend's imagination to picture.

I think I must write you a paper on "Physic for Farmers." One of your late editors asked me once to write an account of the epizootic and its treatment. I had had no experience in the disease then; but I presume the epidemics to which children are liable are equally worthy of attention in your columns.

Carmel Valley, Monterey. E. W. BERWICK.

The Walking Cure.

He has passed Atlanta, Ga., and gone to Topeka, Kansas.—De Mahler—a man who has traveled around the world and all over it on foot. He walks for pleasure. Sometimes a wagoner on the road accosts him with "Stranger, want a lift?" He always replies, "No; rather walk," and some miles on passes the home of the wagoner, who by this time has his wife and children out to look at the man who had rather walk than ride. De Mahler goes trudging on, like the wandering Jew. He has put 40,000 miles behind him since 1862, and has acquired such a momentum now that he can't stop. He must walk to be happy. Of course he stops sometimes for rest and refreshment and sleep, but 'tis only a halt. An Atlanta editor took De Mahler to his house and got some particulars of his walks in life out of him.

De Mahler is a Virginian. He has estates that yield him such an income as enables him to go where he pleases and enjoy himself in his own way. He was wounded in the beginning of our war, and when his wounds healed he was bent nearly double and was totally unable to walk. He was rolled up almost like that being which turns itself into a ball and wheels from place to place. He went to Paris to get straightened out. The surgeons operated upon him; but, after a fair trial, they couldn't make his head and feet stay at their respective ends of the man. At length they told him that nothing could effectually cure him but walking. He resolved to try it. He told his doctor that he was going to walk out of Paris and leave France on foot. His doctor told him he was crazy. He, however, commenced the journey, and made only 104 yards from his lodgings the first day, with the aid of a stick. The doctor tended him two weeks on his trip, that is, until he got out of Paris. He had then begun to improve, and was filled with a glorious hope. He put his whole soul into his walk. In a month he was on the sunny slopes of the Pyrenees and had begun to straighten up like a man. He walked on, and on, and on. At length he was entirely cured and strode with a firm tread. Thus he walked along the world and across it, and became intensely interested in his travels. He sailed across the seas, but walked the decks of vessels in order to keep his foot in. On land he seems to walk as naturally as the winds blow and the streams flow, and now he can't stop. He makes pencil sketches of the best scenes and remembers every place he has been in and the name of somebody he met and talked to. He is thoroughly cured of his war wounds, but many lazy people might think that the cure is worse than the original affliction.

Domestic Economy.

Useful Recipes.

Yeast that will Keep Two Months.

Parse three or four medium sized potatoes and boil till perfectly soft; boil a handful of hops in a separate dish. Mash the potatoes, strain the hop water, and put in with a large tablespoonful of salt, and two tablespoonfuls of sugar. When nearly cold add half a cup of home-made yeast or two tablespoonfuls of brewers' yeast. Put in bottles or a stone jar, and set in a cool place. Half a cup will raise a large loaf.

Graham Pancakes.

One pint of sour milk, one teaspoonful of soda, one teaspoonful of salt; thicken with Graham flour. Let the batter stand 20 or 30 minutes before baking.

Another very good way is to mix a batter at night, with warm water and yeast, the same as for buckwheat, and in the morning it will be light and ready to bake.

Pumpkin or Squash Pudding.

Prepare the same as for pies, and bake in a pudding dish without crust. A good recipe is the following: One cup of stewed pumpkins or squash, one quart of milk, three eggs, a little salt, sugar to sweeten to taste; flavor with ginger, nutmeg or cinnamon; put in a pudding dish, and bake about an hour in a hot oven.

Rice Pudding.

One cup of boiled rice, three pints of sweet milk, three eggs, one cup of sugar; flavor with nutmeg or lemon, and bake from half an hour to an hour.

Indian Meal Pudding.

Scald three pints of sweet milk, and thicken with two-thirds of a cup of corn meal; when nearly cold add three eggs, two-thirds cup of molasses or sugar, one teaspoonful of salt; flavor to taste; if wished, add a piece of butter the size of a hickory nut. Bake slowly from an hour and a half to two hours. Serve hot, with or without sauce.

Sponge Cake.

Three eggs beaten very light, one and a half cups of sugar, two cups of flour, one half cup of cold water, half teaspoon of soda, one teaspoon of cream tartar, half teaspoon of salt; flavor with lemon.

Ginger Cake Without Eggs.

One-half cup of sour milk, half cup of sour cream, one small teaspoon of soda, one good teaspoon of salt, two-thirds cup of molasses, one good teaspoon of ginger; or, take one cup of sour milk, and instead of cream a piece of butter the size of an egg.

Choice of Milk.

Cow's milk differs greatly in quality, some being rich and other thin and watery. In choosing a family cow it is well to bear this in mind, and to select only those that are healthy and give the very best milk. They should also be fed on the best of food, and allowed pure soft water to drink. The practice of feeding cows on garbage, swill slops, distillery feed, and keeping them confined in close, filthy, unventilated stables, is one which seriously deteriorates the milk, and should ever be avoided.

Those who live in cities cannot of course keep cows, so they must depend on the market for their supply of milk. In such cases insist on having the best article, and refuse to use that from distillery-fed cows, or that diluted with water. A little attention to this subject will enable any one to secure a good article. It is the laxity of purchasers of food in not demanding the best that makes it so easy for the dealer to palm off adulterated and inferior articles upon thoughtless people. If the poor would do this, it would improve their own and their children's health wonderfully. The milk supply of a city has a great deal of influence for good or evil on the health of the children. In England this question is getting to be a very important one. The *Food Journal* says that "perhaps the most serious and destructive change in the nutrition of the poor is their almost total privation of milk. Infantile sickness and mortality depend largely on this want." There the occupation of mothers in factories and workshops deprives many thousands of infants of their natural food—breast milk.

ORANGE CAKE.—One cup of powdered sugar, half cup of butter, three eggs, two cups of flour, half cup of sweet milk, half teaspoonful of soda, one teaspoonful cream of tartar. Rub the sugar and butter together to a cream, beat the yolks and whites of the eggs separately. Bake in jelly tins. Squeeze the juice and grate the rind of one orange, and powdered sugar enough to make it stiff enough so that you can spread it between the layers of cake; also add the white of one egg beaten to a stiff froth. This will generally make enough to spread between the four layers of cake and over the top.

SPONGE CAKE.—Six eggs; the weight of six eggs in sugar, and the weight of four in flour, with a lemon extract, or a little grated lemon peel; a little salt, and a spoonful of baking powder.

RYE BREAD is made like wheat, with one exception—the loaves are made quite soft. As little flour as possible is used in molding.

Large advertisements at favorable rates. Special or
 reading notices, legal advertisements, notices appearing
 in extraordinary type or in particular parts of the paper
 inserted at special rates.

Subscriptions payable in advance.—For one year, \$4;
 six months, \$2.25; three months, \$1.25. Remittances
 by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in
 their renewals to the Press promptly as regularly as
 the year comes round. It saves us much expense in
 commissions for collections and renewals. May we not
 request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this
 paper to persons who we believe would be benefited
 by subscribing for it, or willing to assist us in extend-
 ing its circulation. We call the attention of such to
 our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set
 in solid type, giving in our columns one-third more
 reading than is contained in ordinary leaded matter.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Valuable Improve-
 ment in Pumps; Quicksilver Furnaces, 97. Estab-
 lishment of a Clearing House; The Quicksilver Fur-
 nace Litigation; Lunar Researches; The Berry Debris
 Bill, 104. A Report on the Cose Mining Region;
 The Talant Patent Circular Slide Valve, 105; Pa-
 tents and Inventions; Notices of Recent Patents;
 General News Items, 108.

ILLUSTRATIONS.—Four Cylinder Continuous
 Acting Pump; Three Cylinder Pump, 97. Talant's
 Balanced Circular Slide Valve for Steam Engines,
 105.

SCIENTIFIC PROGRESS.—A Novel Lecture on
 Electricity; A Newly Discovered Force(?) Birds with
 Teeth; The Lion "A Pretentious Humbug," 99.

MECHANICAL PROGRESS.—The Mechanical
 Age; The Use of Belts; A Perpetual Clock Run by
 Electricity; Phosphor Bronze; Foundry Charcoal,
 99.

MINING STOCK MARKET.—Sales at the San
 Francisco Stock Board; Notices of Assessments;
 Meetings and Dividends; Review of the Stock Mar-
 ket for the Week, 100.

MINING SUMMARY from various counties in
 California, Nevada, Arizona and Colorado, 101-8.

USEFUL INFORMATION.—Edible Birds' Nests;
 Extracting Oil from Bones; A Monster Boiler; Age
 and Object of the Pyramids; Roman Iron Furnaces;
 How to Cill a Mill Spindle, 103.

GOOD HEALTH.—Typhoid or Remittent Fever;
 The Walking Cure, 103.

DOMESTIC ECONOMY.—Useful Recipes; Choice
 of Milk; Orange Cake; Sponge Cake, 103.

MISCELLANEOUS.—The Smelling Ores of Inyo
 Co.; Yuba County Gravel Mines; The Mines and
 Workingmen; The Mining Debris Question; Gasone
 Valley; Belmont Machinery; The Valley of San Juan;

Establishment of a Clearing House.

After considerable delay in the consideration
 of details, a clearing house has finally been
 established in this city. How a great money
 center like San Francisco has so long trans-
 acted business without this labor saving insti-
 tution is to be wondered at. Clearing houses
 have now come to be an acknowledged neces-
 sity in large cities, and prove a great conveni-
 ence to bankers, brokers and merchants. The
 custom of employing clerks, like so many pack
 mules, to transport specie from one bank to
 another, under the operation of the
 clearing house, he done away with. Hereafter
 the adjustment of daily balances between the
 different banks will be accomplished simply by
 the transfer of checks.

The following officers of the clearing house
 have been elected: President, Milton S.
 Latham, of the London and San Francisco
 bank; Secretary, Ignatz Steinbart, of the Anglo-
 Californian; Clearing House Committee—D.
 O. Mills, of the Bank of California, F. Low,
 of the Anglo Californian, A. McKinley, of the
 Bank of British North America and Homer
 King, of Wells, Fargo & Co.

SEVENTY corpses have so far been recovered
 from the Jabin colliery, Belgium. The earth is
 constantly falling in, and the search proceeds
 slowly, under circumstances of great danger.

The Quicksilver Furnace Litigation.

A suit was instituted in the United States
 Circuit Court about 18 months ago by R. F.
 Knox and Joseph Osborn against the Great
 Western quicksilver mining company, for in-
 fringement of certain patents issued to them
 for improvements in roasting furnaces for the
 reduction of cinnabar.

The Great Western quicksilver mining com-
 pany built their first furnace in the winter of
 1873-4 and commenced reducing cinnabar in
 the spring of 1874. This furnace was claimed
 to be an infringement of their patents by the
 plaintiffs, but not admitted by the defendants.
 Issue was joined and the trial began in this
 city on the 21st of January last, to determine
 the points in dispute.

In their case the plaintiffs put in evidence
 their patents, proved the great utility of their
 inventions, showing a great reduction in cost
 of reducing the ores of mercury by the con-
 tinuous working furnace, and the more effectual
 saving of the mercury over any furnace used
 before the advent of the Knox & Osborn
 furnace.

The defence set up was, that the patents were
 wrongfully issued to the plaintiffs, being a
 combination of old devices, not patentable; and
 further, if the patents were held good, they
 (the defendants) had not infringed them.

This being the first attempt to sustain these
 patents, and there being some 15 to 20 furnaces
 built which are claimed as infringements, the
 case created great interest, and was to some
 extent a combination of all the interested
 parties in the State to break the patent, and
 thus end the possibility of claims against other
 companies being made in the future. In the
 course of the trial, every furnace which was
 ever heard of which was thought to contain
 any one of the devices of the Knox & Osborn
 furnace was brought forward and discussed by
 the experts, who gave learned opinions of all
 the old furnaces and line kilns ever sketched
 in books or even heard of yet nothing was
 produced showing a continuous working quick-
 silver furnace until the Knox & Osborn fur-
 nace was built.

It also appeared in evidence that since this
 furnace has been in operation no intermittent
 furnace of the old style has been built, showing
 a great revolution in the manner of reducing
 mercurial ores, by which lower grade ores are
 now profitably worked, and many mines now
 paying expenses while being opened, which
 could not be worked with the old style of fur-
 nace.

After an elaborate charge by Judge Sawyer,
 the case was submitted to the jury on Monday
 last, who after a short deliberation rendered a
 verdict sustaining every claim submitted to
 them in the plaintiff's patents, and also found
 all the claims infringed as charged.

This may be regarded as a test case, having
 been very thoroughly and vigorously contested
 on both sides, and although there may be
 other suits embracing the same points of law
 as this, it is probable that the result in this
 one will be held as conclusive.

Lunar Researches.

An interesting lecture was delivered in the
 School of Mechanic Arts course on Saturday
 evening last, by Professor Frank Soule, on the
 subject of "Recent Researches on the Lunar
 Surface." After referring to the marvelous and
 often fantastic theories and superstitions of the
 ancients concerning the moon he passed to the
 time of Galileo, when the wonderful genius of
 that astronomer invented the telescope, and
 opened a new field of investigation to mankind.
 With his rude instrument of only 30 diameters
 of magnifying power, Galileo could perceive
 but the bolder and more general features of the
 disc, while we will employ ere long a telescope
 which the scientific progress of three centuries
 has perfected, with a power of several thousand
 diameters.

In using the immense telescopes of modern
 times, one is surprised at the exceedingly small
 area that can be examined at one time, and by
 the great diminution of light which appears to
 take place. A careful survey of the surface
 fills one with astonishment that, "the placid,
 silvery moon" should be changed into a ragged,
 gray, wrinkled, and pockmarked heavenly
 beauty.

On turning to the brighter portions we find
 everywhere mountains, volcanoes, crevasses
 and precipices of vast height or depth. It
 seems to be a picture of desolation, enthroned
 upon a pedestal of ashes. Those mountainous
 parts reflect a brilliant light on account of their
 volcanic nature, the rocks being often smooth
 and polished, and their jagged surfaces giving
 them power to catch and throw light in every
 direction. The southwestern portion is espe-
 cially volcanic in its appearance. On close
 examination, however, we find long ranges of
 mountains exhibiting no signs of volcanic
 action, but in many respects similar to the
 Sierras, much steeper on one side than the
 other, and apparently formed by similar forces,
 though as a rule the volcanic element prevails.
 Many of these mountains are of immense size;
 thus Clavius is 120 miles in diameter, has an
 area of 12,000 square miles, and turrets on its
 walls shooting to an altitude of 16,000 feet.

We next notice the frequent occurrence of
 ringed mountains, not more than 10 to 15 miles
 in diameter, and almost perfectly circular in
 form. They are found alone upon the level
 country, or in groups, and even upon the
 ridges of the walled plain. There are also
 craters and pits, which differ chiefly from the
 others in their smaller dimensions. There is
 also another prominent feature which has puzzled
 astronomers, even to the present day. From
 many of the ringed mountains, notably
 from Tycho, Copernicus and Kepler, are radia-
 tions, extending in some cases hundreds of
 miles, which at the full of the moon glisten
 with a remarkable brightness. They shine as
 brilliantly under the oblique as under the ver-
 tical rays of the sun—a fact yet unexplained;
 they pass over the tops and through the craters
 of volcanoes, and down through the valleys in
 an uninterrupted course. Of the many theories
 concerning them, perhaps the most reasonable
 is that they are veins of matter ejected from
 below during some great volcanic or earthquake
 disturbances, and in many respects they re-
 semble our own trap dykes and seams.

Since the time of Galileo, astronomers have
 painfully, patiently and perseveringly mapped
 every detail of the moon's surface, until we
 have lunar topographical charts more accurately
 constructed than any hitherto constructed of
 the earth's entire surface. Photography has
 recently aided largely in this work.

By careful experiments it has been proven
 that the light of the full moon is only 1 600,000
 part of that of the sun, and that she gives only
 one-sixth as much light as would a pure white
 disc; therefore, she is nearer black than white.
 An equal sized globe of fire-brick or clay thrown
 into the orbit of the moon would furnish us
 with light as bright as our own luminary.

As early as 1700 efforts were made to ascer-
 tain if any heat came from the moon, her rays
 being concentrated by means of a lens upon the
 bulb of a thermometer, with no effect, however,
 and other and later trials with improved appa-
 ratus gave the same result, or in some cases
 indicated that the moon was shedding negative
 heat, or cold. It was only after the invention
 of the thermopile that evidences of lunar heat
 were discovered. The amount was excessively
 small, however. Lord Rosse with the aid of
 his three-foot reflecting telescope and Thomp-
 son's galvanometer, shows little, if any, of this
 heat comes from the interior of the moon; or,
 in other words, that the body of that luminary
 would be cold but from the heat absorbed from
 the sun. This borrowed heat has been shown
 to raise the exterior temperature of our satel-
 lite to at least 50 deg. Fahrenheit. As the sun's
 heat and light cease to fall upon her surface
 and are lost for 15 days at a time, and the
 remaining heat being radiated into space, the
 alterations of temperature must be something
 startling, and the changes in the physical
 features of the body produced by the enormous
 expansions and contractions of her outer sub-
 stance must be great and very destructive.

Professor Soule will deliver another lecture
 upon different phases of this subject some time
 in March next.

THE FRYER PROCESS ON PEAVINE ORE.—We
 have been shown, says the Gold Hill News, the
 results of the working of 18 pounds of ore from
 the Golden Fleece mine in Peavine District, by
 the Fryer process, in Grass Valley, California.
 This ore, although rich and giving excellent
 assays, has always heretofore defeated every
 effort made for its successful reduction. Its
 combination of materials is one of the most
 stubborn on the coast to overcome. It seems,
 however, to make no difference with the Fryer
 process, the ore working with the same ease
 and successful results as the free ores of the
 Comstock.

The result gave a return of \$54.98 per ton in
 gold and silver, there being only \$2.48 gold.
 The value of the bullion was \$1.23 per ounce
 —\$1.17 58-100 in silver, and .06 20-100 gold,
 there being no base metal whatever in it, prov-
 ing as conclusively as it is possible that the
 process makes a clean sweep of all the base
 metal. Not satisfied with the statement, Mr.
 Henry had the bullion assayed and tested in
 the most thorough manner possible by Mr.
 Gilbert McM. Ross, of this town, every test
 failing completely to find any base metal what-
 ever.

This is certainly good news for the stock-
 holders of the Golden Fleece, who rejoice that
 they have at last found a process by which
 their ores can be treated successfully. They
 have a large ledge and almost inexhaustible
 bodies of the ore, easy to get at and extract;
 and all they now await is the test of the ore in
 large quantities and the erection of proper
 character of reduction works to add another to
 the many rich mines of Nevada.

EGYPT AND JAPAN.—It is a fact worthy of
 record that the very first to arrive on the ground
 of the foreign contributions to the Centennial
 was that of Egypt, the oldest of known nations
 making her friendly offering to the youngest.
 Speedily upon this came the practical demon-
 stration of the friendly spirit of Japan—19 cars
 loaded with her exhibits having reached the
 Centennial grounds on the 17th of December.
 The North American thinks there is a better
 illustration of the importance of the exposi-
 tion to be gleaned from these two items than
 from a volume of argument.

The postal telegraph bill has made its re-
 appearance in Congress, having been intro-
 duced in the House by Representative Luttrell.

The Berry Debris Bill.

On another page of the Press we print an
 article from the Oroville Mercury concerning
 the bill introduced in the Assembly by Mr.
 Berry, of Sutter county, for the appointment
 of a commission to investigate the mining de-
 bris question. Below will be found the full
 text of the bill:

WHEREAS, The detritus washed from the hy-
 draulic mining claims is filling our river chan-
 nels, destroying navigation, and irreparably in-
 juring large portions of our valley lands; and
 whereas, this deposition of detritus is rapidly
 increasing, threatening greater damage in the
 future, even menacing the existence of some of
 our cities, towns and villages; and whereas,
 the great interest involved being the two chief
 industries of our State, the agricultural and
 mining, neither of which can be injured with-
 out inflicting injury upon the other and upon
 the State; and in order to enable a future Leg-
 islature to act intelligently, and by wise legisla-
 tion secure a just solution of the subject, and
 thus avert the danger impending; therefore the
 people of the State of California, represented
 in Senate and Assembly, do enact as follows:

SECTION 1. Within ninety days after the pas-
 sage of this Act, it shall be the duty of the
 Governor of this State to appoint three Com-
 missioners, one of whom shall be a practical
 mining engineer, one a competent engineer
 from the agricultural district, and one a com-
 petent civil engineer.

SEC. 2. It shall be the duty of the Commis-
 sioners appointed in accordance with Section 1
 of this act, at such times as they may choose,
 to visit the principal hydraulic mines upon the
 headwaters of the Sacramento river, Feather
 river, the Yuba river, the Bear river, the Ameri-
 can river, and such other streams as they may
 deem necessary, for the purpose of ascertaining
 the amount of detritus annually discharged, by
 process of hydraulic mining, into the streams,
 water-courses, and bays of this State. They
 shall also collect information as to whether
 this class of mining is on the increase or de-
 cline.

SEC. 3. It shall be the duty of the Commis-
 sioners to collect all information attainable by
 them as to the amount of gold produced from
 the hydraulic mines, the cost of extracting the
 same and such other information thereto as
 they shall deem proper to lay before a legisla-
 tive body.

SEC. 4. It shall be the duty of the Commis-
 sioners to visit the Sacramento, the Feather,
 the Yuba, the Bear, and the American rivers,
 and such other streams, water-courses, or bays
 as they may deem necessary, at different
 points, for the purpose of ascertaining, as near
 as practicable, the height (?) depth to which
 the streams visited by them have been filled,
 the amount of damage done to the lands along
 and adjacent to the streams, by the deposit of
 detritus from the mines.

SEC. 5. It shall be the duty of the Commis-
 sioners to make approximate estimates of the
 capacity of the streams for retaining the debris
 discharged into them, the proportion that
 passes into tide-water, and such other approxi-
 mate estimates relative thereto as they shall
 deem proper to embody in their report.

SEC. 6. It shall be the duty of the Commis-
 sioners to suggest a plan or plans whereby the
 detritus from the mines may be prevented from
 finding its way into the rivers and bays, and
 for this purpose they shall have the power to
 make surveys, take levels, and submit estimates
 of the probable cost of executing the plan or
 plans submitted by them. They shall also
 collect all other information relative to the
 duties prescribed by this act as may, in their
 judgment, guide or aid a legislative body in
 framing [a] law for the abatement of the evils
 set forth in the preamble to this act.

SEC. 7. It shall be the duty of the Commis-
 sioners to compile all the information collected
 —all estimates, surveys, plans and suggestions
 —in a brief and concise form, and report the
 same to the Governor, on or before the 1st day
 of December, A. D. 1877.

SEC. 8. The Governor shall cause the same
 to be laid before the Legislature, whenever he
 shall be notified of its organization.

SEC. 9. Each of the Commissioners appointed
 under and by virtue of this act, shall receive
 the sum of — dollars for all services herein
 required.

SEC. 10. When the Governor shall receive
 the report of the Commissioners, herein pro-
 vided for, he shall certify that fact to the Con-
 troller, whereupon the Controller shall draw
 his warrant upon the State Treasurer for the
 same; and the Treasurer shall pay the warrant
 thus drawn out of any moneys in the Treasury
 not otherwise appropriated.

SEC. 11. This act shall take effect and be in
 force from after its passage.

STOCK BOARD FOR EASTERN OREGON.—Owing
 to the fact that the capitalists of Portland are
 about to establish a mining stock board to han-
 dle Eastern Oregon mining stock, the Baker
 City Democrat urges the mine owners of East-
 ern Oregon to incorporate a stock board in that
 city, not merely for the purpose of stock trans-
 actions, but with a view of gathering authentic
 information in relation to the mines and to be
 able to make interested parties acquainted with
 the mineral resources of that section. It is a
 good suggestion, and might be acted upon to ad-
 vantage.

A Report on the Coso Mining Region.

We give herewith a report on the property of the Coso Consolidated mining company, Inyo county, made by Mr. J. S. Phillips, M. E., (author of the "Explorers", "Miners" and "Metallurgists' Companion.") The report will be of interest to those interested in the Coso mineral region, as it gives an account of the general characteristics of that new district, as well as the details concerning the mine reported on:

Geographical Position.

The Coso Consolidated mines are located in the county of Inyo, California, about two miles north from the town of Darwin, about one day's travel by stage from Caliente railway station, and two days from San Francisco by rail and stage.

Geological and Mineralogical Features.

This property and most of the other mines of the district are located in Coso mountain, which is chiefly composed of the highly tilted stratification of the older clay, slates, limestones and magnesian limestones, interlaced by dikes of feldspathic rocks and metamorphosed by the close proximity of subterranean heat, as shown by a surface outcropping of lava in its vicinity, at just half a mile below. This Coso range is evidently a continuation of the Inyo, which also trends southerly, and is similarly composed both in its rocks and metallic mineral combinations.

The Coso veins also closely resemble those at Cerro Gordo, in the Inyo range, and do not always conform to the divisions of cleavage in the strata, but have generally taken independent diagonal fracture, somewhat after the order and comports of true fissure veins.

The minerals are also similarly composed, being mostly silver-bearing sulphuret and carbonate of lead, with congenerial ferruginous stains, very generally disseminated therein.

General Character and Quality of Veins.

There are two strong veins already discovered—the Raleigh and Bella Union. The Raleigh lies about 1,000 yards southeast of the Bella Union, and somewhat higher in the hill. It bears 38 deg. east of north, dips 80 deg. westward and has been worked to some slight extent by a shaft on the vein. So far as seen, it appears to be about three feet wide and contains interesting ferruginous stains throughout, with occasional stains of the sulphuret and carbonate of lead. It deserves further proof by tunnel on the course of the vein, which I think can be easily traced to much lower ground at a slight distance northward.

The Bella Union vein has been much more extensively explored by a shaft, 110 feet deep, two levels and a winze communicating from level to level. This vein has an average bearing of about 30 deg. east of north, is not generally less than 6 feet wide, and dips 55 deg. westerly. The surface cropping of the vein exposes mineral just in one place only, some 50 feet southward from the shaft, and in sinking the shaft comparatively little of value was discovered, but in driving the bottom level an abundantly mineralized vein was gradually discovered at 30 feet northward, where it became and continued really valuable for at least 130 feet beyond this point, when it, however, temporarily fell off in value for a few feet, but not in size or strength, for, although the lode did not contain the mineral, it looked as well defined and even more interesting in the north end, or drift, than at any other place, having distinct laminations parallel to the smooth and well marked corrugated slickenside walls, which has accompanied the vein backward, and still retained the heavy and congenerial ferruginous stains throughout.

I am informed that since my return, even greater value of lead minerals have been again attained in this drift.

Quantity and Value of the Ore at the Surface and in the Mine.

The amount of ore now lying at the surface, on the 1st of December, 1875, equalled at least 800 tons, which I estimated would realize about 260 tons of argentiferous lead bullion. As to its value, I may say that 15 assays from selected stones, made for both lead and silver, afforded an average of 54 per cent. lead and \$109 per ton silver, which would have smelted, allowing for practical loss of lead, at about the rate of two tons of mineral and \$218 of silver for each ton of bullion produced.

It is, however, difficult to estimate from mere assays, without the actual large scale smelting examples, the correct value of the resultant bullion smelted from such mixed varieties of lead and silver ores, but I think it may be safely placed at from \$180 to \$200 of silver per ton of lead bullion. The lower one of these, the \$180 of silver per ton of lead bullion, can be sold at San Francisco for both lead and silver at about \$220 per ton.

The cost of the mining and smelting of this and future ores into such bullion, and delivering it at San Francisco, need not exceed \$105 per ton of bullion produced, and therefore the present surface ore piles already broken should realize the total profit of \$27,300.

This ore was all excavated in simply driving the bottom level of six feet in height through the 130 feet of mineral before stated, and in sinking the winze 54 feet deep by six wide from the upper level through the same deposit of ore to the lower level, which exposes and

equals a superficial sectional area on the vein of only 1,104 feet.

Now, by taking the above as a safe average value of that portion of the vein already thus promptly obtained, and estimating what has been laid open by allowing only (according to the practice of the most careful miners) 30 feet above and 30 feet beneath this level, you will be much pleased to know that you have 7,800 superficial feet remaining in section (130 feet by 60 feet), and the consequent profit value, over all expenses, of \$192,880.00, which makes the total profit value already in sight, above and below the surface, \$220,180.00, regardless of the lode showing continuous value, still being developed by the north drift and the deeper future levels on the splendid abutment of mineral just alluded to in these valuations.

Suggestions for Development of the Mine.

As you have already practically laid open and hoisted to the surface sufficient ore for running one furnace 12 months, it will be well to continue driving the north level through the ore in that direction so as to prove how far it continues, and if it should continue far it will be most advisable to sink a vertical hoisting shaft through the soft country or bedrock over the vein, so as to cut it just in the body of mineral for better ventilation and greater convenience, speed and economy in extraction. It will be also advisable to keep driving the bottom level southward by a small corps of men under the large body of ore seen at the surface just south of the shaft, and to explore the vein for other deposits.

Best Method for Reducing the Ores into Metal.

The constitution of the ores are, at the present time, favorable for smelting, every necessary element being present in very suitable proportion for reducing the comparatively moderate quantity of the most refractory sulphuret of lead. The carbonate of lead smelts easily in itself and favors the galena, whilst there is sufficient carbonate of lime as a reducing flux for

ficial purpose of concentrating such ores for the enrichment of your bullion, as this would add but little to the expenses of smelting and procure a higher value, not only for what has been thus added, but for all the silver contained therein.

The Tallant Patent Circular Slide Valve.

Perhaps comparatively few engineers are aware of the enormous waste of power, and consequently of money, caused by imperfect and unbalanced slide valves in steam engines; yet so important has this matter been considered that some 200 patents have been granted on improvements and inventions for the better distribution of steam in steam engines and methods of reducing the power required to operate the same. The countless number of devices by which it has been attempted to evenly balance the pressure on the top of the common slide valve have cost fortunes, and few of the many have proved of value. When the inventor has been successful in overcoming this pressure, it has been at the sacrifice of simplicity, and the care required to keep them in order has created prejudices against most all others which have been proposed.

The well known English engineer, Mr. W. G. Beattie, in an article published in the *London Artisan*, gives the following results from a number of careful indicator tests made by him: "An ordinary locomotive slide valve ten inches long by seventeen inches in width makes an area of 170 square inches under steam pressure for an engine of seventeen inch cylinders, at 126 pounds pressure of steam in the valve chests; this amounts to a pressure of 22,000 pounds. From this must be deducted the pres-

TALLANT'S BALANCED CIRCULAR SLIDE VALVE FOR STEAM ENGINES.

the iron oxide to aid the reduction of the sulphuret of lead by its strong affinity, causing the double sulphide reaction with iron. For these reasons the preliminary roasting of the sulphuret of lead will be unnecessary, provided the heavy slugs are closely watched, and occasionally recharged, both as a valuable fluid flux, and to reduce the stubborn sulphide of lead, which they sometimes retain, to metal.

As the mine is deepened I think the carbonate of lead will lessen and sulphuret prevail, when it will become necessary to roast before smelting to metal.

If I were smelting this ore I should use a cheaper and more efficient furnace than has been used in this region, but as the journeymen are familiar with those used at Cerro Gordo, it may not be advisable to introduce other modes.

Summary of Facts Favorable to the Mines.

The mines are located in a dry climate, and sufficiently high for the drainage of the ground around the vein, so that little pumping power will ever be required. The enclosing rocks are soft and easily mined.

The vein itself can be also cheaply worked, and is unusually well defined, having the laminations and walls of a true fissure and a strongly corrugated slickenside, which is the best possible proof of great extent of fissure.

Costs for mining, carriage by descending grade and smelting are comparatively light, and can be carried on all the year. The large amount of valuable ore at the surface and in sight below, both in length and probable depth, and unmistakably evidence for long continuance.

The costs for smelting are not very heavy, as charcoal can be obtained at 32 cents per bushel.

The railway is gradually approaching, and the carriage of bullion thus saved will be added to the gradually increasing profits.

The small amount of labor expended for the superior results obtained in such a short time.

In conclusion I may therefore say that few mines have been opened under more favorable auspices, or produced more for the extent worked, and with the foregoing facts before me I can see no reason why you may not disburse dividends in a very short time after the furnace you have already leased is in successful operation.

I would still further suggest to you the great advantage that would accrue from the buying of rich silver ore from prospectors or getting a rich silver ore vein, for the very bene-

to which it has been applied, with even less consumption of fuel than before. The greatest loss of power with the ordinary slide valve is when the piston is just completing its stroke and has no control over the crank. At this time, the cylinder being empty of steam, there is no lift to the valve from back pressure, while the pressure on top of it from the steam in the boiler is even greater than ever. With this invention it makes no difference where the piston may be, as there is no pressure on the valve at any time. That this is the case may be plainly seen in the motion of any engine fitted with the circular slide valve.

Conceding the value of the principle on which this valve is constructed, practical engineers have objected to its supposed liability to ent and wear and leak steam, and thus become useless in a short time. The experience of several years has proved this objection to be without any foundation in fact. By using any one of the self-feeding oil cups now in general use, a small but constant supply of oil may be furnished the valve, which in three years' constant use has prevented any perceptible wear whatever, the tool marks not having scored out in that time or the valve having even become bright. Practice has proved also that the valve will not ent, even if oil is withheld from it. It will groan and give fair notice of the neglect, and in cases of gross negligence, will stick fast like a hoggy wheel without oil, and the stem twist off. With the most ordinary care, and with less than half the supply of oil required by the common slide valve, there is never any trouble whatever.

The advantages claimed for this device are: First, A total absence of unbalanced pressure and consequent saving of friction. So complete is this that the valve can be shifted with one hand on any sized engine under steam pressure with perfect ease, which would be impossible with the ordinary valve. Second, Consequently a celerity of movement which no other device gives. The ease with which the crank passes the center must be seen to be appreciated. Third, Instead of requiring a large portion of the steam power in the boiler to move the valve, as in the case with the old style, this valve is self-moving, the shape of the grooves being such that the instant steam is admitted it moves itself, the eccentric simply starting, regulating and checking it. Fourth, Instead of the steam being admitted on the top and pressing the valve down, this device is so arranged that the steam enters on each side below the center, lifting the valve up, thus to a certain extent overcoming the weight of metal of which it is made, and reducing the force required to move it to an absolute minimum. Fifth, The arrangement for cut-off, expansion of steam while working in the cylinder, and releasing, are so perfect that all of the force of the steam in the boiler is reserved for labor or duty, the valve simply forming a direct tube from the boiler to the head of the piston in the cylinder, capable of being shifted many times a minute to the other side without any waste of power whatever; hence, much less steam is required and consequently much less water to be evaporated or fuel to convert it into vapor.

This invention is so simple as to be readily understood by a glance at the cut. It is a complete substitute for the common slide valve now in universal use. It is adapted for locomotives, steamboats, propellers and stationary engines, an improvement that no user of a steam engine can afford to leave unexamined. These valves are manufactured and applied to existing and new engines by W. W. Hanscom, of the Hope Iron Works, at the Potrero, where Mr. Hanscom will be pleased to show the action of the valve and many testimonials of its use where it has been in perfect condition for years without repairs, wear or deterioration.

JAPANESE AGRICULTURAL COLLEGE.—According to the *Springfield Republican*, our agricultural college experiment is to be repeated in Japan. The Japanese government have been for some time endeavoring to engage President W. S. Clarke to found for them an agricultural institution after the plan of the one at Amherst. The trustees have granted him a year's absence, and such arrangements will be made that it is believed his going will not prove injurious to the Massachusetts college. Ample capital will be furnished. Col. Clarke is authorized to engage his assistants, and in every way to conduct the undertaking after his own methods. A special minister has been in the country effecting the arrangement.

THE San Francisco art association has just closed a very meritorious exhibition. Those who have been in the city during the past few weeks without visiting its room have missed such a treat as they cannot realize. The school of design for pupils over 14 years of age commences a new term on Monday next. Address Virgil Williams, at the rooms of the association, No. 313 Pine street, San Francisco, for particulars.

SENATOR SARGENT has introduced a bill which ought to be, and probably will be soon passed, and thus abate the silver nuisance, from which workmen and others suffer on the Pacific coast. He proposes to make the trade dollar a legal tender at its nominal value for any amount not exceeding \$20 in any one payment; the silver half-dollar a legal tender for amounts up to \$10; and the 25c., 20c. and 10c. coins a legal tender for single payments not exceeding five dollars.

Jersey District.

James A. Hill, R. C. Reeves and S. J. Chambers left here last Saturday, says the *Silver State*, on a trip to Jersey district, which is attracting considerable attention at the present time. They returned last evening and furnished us the following relative to the new camp:

Jersey district is situated about 60 miles east of south from Winnemucca. There are about 100 men at present in the camp, and several new buildings are in course of erection, among them one intended for a hotel, which is being built by Messrs. Laveaga and Hawley of Unionville.

The Mine

Was discovered about two years ago by Len Tremble, of Galena. It has paid its way from the beginning, the ore having been shipped to California and Europe for reduction. It was purchased of the original owners last November by Frank Hamilton, J. Sevenoaks and others for \$40,000 in coin and one-tenth of the capital stock. The course of the vein is north and south, dipping west. It is from 10 to 12 feet wide, and carries on an average four feet of galena and about five feet of carbonate of lead. A ravine runs at right angles with the course of the ledge. From this ravine the vein is prospected north by a tunnel 300 feet long, and south by a tunnel 50 feet long. A shaft is sunk on the ledge in the south tunnel to a depth of 25 feet below the level. The vein is of uniform width as far as prospected and is well defined. The average assay of the cropings is \$195.63 silver to the ton and 76 per cent. lead; of the dump \$78 per ton in silver and 33 per cent. lead; at the bottom of the shaft \$126.69 in silver, and 70 per cent. lead. The quantity of ore on the dump is estimated at 1,500 tons.

The Furnace

Is completed and its net capacity is 40 tons of ore a day. It will require from 800 to 1,000 bushels of coal daily to run it to its full capacity. It will be fired up on the 4th of February, from which time it is expected an average of 10 tons of bullion will be produced daily. A large force is now engaged in chopping wood and burning coal in the Austin range, about 25 miles southeast of the mine, and another party of choppers and coal burners will be set at work shortly in the second east range, south of Clark's ranch, where there is an inexhaustible supply of nut pine and cedar wood.

Other Prospects.

The ledge has been traced 3,000 feet north of the Jersey company's works, and south to a considerable distance. An extension of the lead is owned by Robert McBeth, and the prospects of finding an extensive body of ore are very encouraging. Mines have been discovered and locations made north and south of the Jersey for three or four miles. When the works are in full blast some 10 or 12 ten-man teams will be required to haul coal to the furnace and bullion to the railroad. They want a post office established at Jersey City, with semi-weekly communication with the railroad, and have signed a petition to that effect.

THE LAW OF INCORPORATION.—Judge Wright has granted a nonsuit in the case of A. P. Needles against J. W. Pearson. The suit was brought to recover damages, sustained by Needles, for being refused access to the books of the Woodville mining company after he had exhibited evidence that he was a stockholder. Justice Joachimsen rendered judgment for Needles for the amount claimed, and the defendant appealed the case to the County Court. Judge Wright decided that the law requires that the original incorporation shall be filed with the County Clerk, and a certified copy be deposited with the Secretary of State. That official is required to send to the company incorporating a certificate that the incorporation law has been complied with. The plaintiff failed to produce such a certificate and prove a legal incorporation, and the court therefore granted a nonsuit.

Rumor states that a narrow gauge railroad is contemplated to connect Sebastopol with Santa Rosa.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of all machinery and furnaces for the treatment of rebellious ores. Office—439 Bush street, S. F.

Rupture.

Use no more Metallic Trusses. No more suffering from Iron Hoops or Steel Springs. Dr. Rowe's Patent Elastic Truss is worn with ease and comfort night and day, and will and has performed radical cures when all others have failed. Reader, if you are ruptured try one of Dr. Rowe's comfortable elastic appliances; you will never regret it. ROWE ELASTIC TRUSS COMPANY, 609 Sacramento St., S. F.

MINING ENGINEER.

A Mining Engineer, with the best of best of references, thoroughly experienced in the opening and superintending of mines and mills, desires an engagement. Address, "MINING ENGINEER," MINING AND SCIENTIFIC PRESS Office, San Francisco.

GOLD, SILVER AND COPPER MINING. Reducing and Concentration Machinery.

Address, FRASER, CHALMERS & CO., Chicago, Ill.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Talbot, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

AUTOMATIC PUMP.

Raises water by compressed air to any height or distance. Windmill can be set at any distance from the well or spring if required to get a good exposure to the wind.

SEND FOR CIRCULAR.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 126 First street, S. F. 24v23

UNITED STATES

Mineral Land Laws, Revised Statutes, And Instructions and Forms under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870; Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim. There is also given the U. S. Coal Land Laws and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

IMPROVED.—Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS and the RURAL PRESS, now have the leaves of both these sixteen page sheets cut and stitched, which is an improvement that all readers of that otherwise inconvenient form of journal will appreciate very much. Every farmer would be a gainer were he to subscribe for the RURAL. It is decidedly a valuable paper, and the SCIENTIFIC PRESS is no less so to mining men.—Inyo Independent.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

THE MINING AND SCIENTIFIC PRESS is one of the best papers published on this coast. It should be in the hands of every miner and mechanic in the State. The issue of last week contained an excellent article on the gold product of this coast.—Oroville Mercury, Jan. 28th.

GIVE YOUR FULL ADDRESS when you communicate on business to this office, especially in returning newspapers. The fact that your name is on our subscription list is of no assistance to us. Without sending your post office address we should have to look over thousands of names to find yours.

[PUBLISHERS' ANNOUNCEMENT.]

MINING AND SCIENTIFIC PRESS

For 1876.

THIS PUBLICATION, SO VALUABLE FOR MINERS, MECHANICS AND MANUFACTURERS,

Will enter upon its THIRTY SECOND Semi-Annual Volume on Saturday, January 1st, 1876. It has ever been and will still continue to be the aim and object of the publishers to make the Press

A Practical and Interesting Journal.

To this end, we aim, through the constant watchfulness of our editors and correspondents, to seize upon everything new in the way of mining and the various processes connected with the saving and separating of the precious metals, and place the same before our readers at the earliest day. It has been well said that

A Newspaper is a Window

Through which men look out upon all that is going on in the world. Our window is a special one, so placed and arranged as to bring within the scope of its vision all that is going on

In the World of Mining, Mechanics and Science.

Without a paper of this kind, the miner or mechanic is shut up in a small room or shop and can know but little of what is going on in the world around him in relation to his particular calling. In this age of rapid progress books are necessarily slow and behind the times. It is only through papers devoted to the specialty which he has chosen that one can be easily apprised of the discoveries and improvements which are constantly being made by his fellow workers, and without a knowledge of which he soon becomes a laggard in the race.

The Value to the Community

Of such publications in disseminating important information, in checking useless and exploded experiments and in instigating important enterprises, can scarcely be overrated. Through them the readings and observations of thousands are collected and collated, and brought directly to the shop or table of the reader, without any effort of his own. For a mere trifle of cost he is regularly furnished with an encyclopedia of just the information he needs—an unbound book forever lasting but never finished.

Nowhere in the Wide World

Is such an aid more needed than by the miner of California. It is needed alike in the mill, in the mine and in the placer. We have here

The Largest Mining Field on the Globe,

Embracing a variety of minerals nowhere else found within the boundaries of a single field. We have here also, men gathered from every quarter of the globe bringing with them the collective wisdom of the world.

Useful, Practical and Directly from the Field

Of labor. The minstiness of hooks has been hushed away, and their minds are stored not only with the experience of the past, but also with the practice of the present. It is to this fact that we are indebted for our present

Able List of Correspondents,

Through whom we are able to promise to our readers so much that cannot be collected in the mere routine of office work. By the aid of such help our editors will be able, during the coming year, to do more than ever in furnishing information which shall be

Fresh, Novel and Interesting,

And which shall comprise all that is known of the latest and best means for saving gold and silver, and for economizing labor and cost in that direction.

Our Illustration Department

Will still continue to form an important feature, and no effort will be spared to make it of the greatest possible local and general interest to our readers. The important matter of

Home Manufactures and Inventions

Will also largely occupy the attention of the publishers and editors, and will be constantly encouraged, as an important means of furnishing employment to those who are seeking our shores, and adding to the wealth of the Pacific coast.

The Large and Increasing Circulation

Of a journal thus devoted exclusively to useful and practical information, speaks more in our behalf than anything we could say of ourselves, and is an encouragement to its further increase, especially in these times of trying and troublous journalism.

The class of readers who are interested in such a publication as this, have no need to be anything more than merely reminded that such journals are necessarily more costly than those of a lighter class, such as are read by the "million" and thrown aside as soon as read. Considering the character and location of the MINING AND SCIENTIFIC PRESS, our rates are as favorable as can possibly be afforded and do justice to the great industries in aid of which we are laboring.

A Handy Map

Of California and the principal portion of Nevada will be furnished free to all subscribers who pay one year in advance, during the year 1876. The map is plain, printed on tinted paper, about 16x20 inches, showing townships in California, and the counties, railroads and principal towns in California and Nevada.

We Prepay the Postage

On all papers sent to subscribers in the United States. SUBSCRIPTION RATES, payable in advance: One year, \$4. Sample copies free to those who will assist in obtaining subscribers.

DEWEY & CO., Publishers,

No. 224 Sansome street, S. F.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, Mexico, Colombia, Canada, Norway, Sweden, British Columbia, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wrttemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, and EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made, by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

California Acclimatizing Society—Location of principal place of business, San Francisco, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of February, 1876, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, room No. 37, Nevada block, northwest corner of Pine and Montgomery streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the fourteenth day of December, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the third day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. W. W. TRAYLOR, Secretary, pro tem. Office, room 37, Nevada block, San Francisco, Cal.

Cherokee Flat Blue Gravel Company—Location of principal place of business, San Francisco, Cal. Location of works, Cherokee Flat, Butte county, Cal.

Notice.—There are delinquent upon the following stock on account of assessment (No. 35) levied on the twenty-eighth day of December, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
O. Weller	1	624	\$31 20
Louis Schmidt	8	128	6 40
E. J. Pfeiffer	10	480	24 00
A. Cassell	17	4,008	230 40
Mrs. E. M. Walton	21	128	6 40
Mrs. Mary W. Farrington	35	144	7 20
Geo. W. Bamage	36	320	16 00

And in accordance with law, and an order of the Board of Directors, made on the twenty-eighth day of December, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, room 13, No. 328 Montgomery street, San Francisco, Cal., on the nineteenth day of February, 1876, at the hour of one o'clock, p. m., of such day, to pay delinquent assessment thereon, together with costs of advertising and expenses of the sale.

O. H. BOGART, Secretary

The Henry Tunnel.

A letter was received here a few days ago from Major Henry, who was then in New York city, stating that he had succeeded in forming his tunnel company, and that a Burleigh drill had been purchased and would arrive here in about 30 days. Our readers will remember that immediately after the departure of Major Henry for the East, we published an article stating that it was his intention to run a tunnel through Treasure hill, and it now looks like he has made the necessary arrangements in the East for carrying out his original plans. We hope it may all prove true, for in the tunneling of Treasure hill depends much the future prosperity of Hamilton and its surroundings. We copy the following from an article we published some time ago, setting forth the plan of operations and benefits to be derived therefrom: "At length we have the promise of having the hidden treasures of Treasure hill exposed to view. Major Henry, with the eye of an engineer, conscious of the great profit resulting from the successful carrying out of the indicated enterprise, has, after the needful surveys, located a 3,000 foot tunnel that, when carried out, will under run the mountain crest some 1,600 feet, and will perfectly expose the three formations that compose it. These rocks are all metalliferous, of the silurian age, with their character fully developed to the depth of 2,100 feet, in this and Cognate districts. First, limestone; second, a shaly slate; and finally a quartzite, the home of fertile ores in Pioche and Cherry creek, that may extend far beyond the 2,100 feet at which it has been recognized. The large amounts of treasure obtained by superficial working are a reliable index of the vast wealth to be derived from exploitation, and it is more than presumptive that Major Henry and his friends, though with no franchise save that bestowed by general law, will in both profit and honor outvie Sutor and his far-famed and much contested works. The projected tunnel will traverse comparatively virgin ground, concurrently with east and west lodes of known wealth, and will currently cut at right angles a number of north and south veins at a profound depth. The Aurora lode, the most conspicuous of this class, will be intercepted at about 1,200 feet in depth, in the quartzite country, and this, with Captain Drake's incline, now down over 600 feet, will be a complete illustration of this remarkable lode. Within a year, at an unimportant cost, and independent of the season, with the appliance of a Burleigh drill, this work can be consummated to the great profit of its operators, and it is highly probable that immediately the current expenses will be defrayed or materially lessened by the extraction of ores from the constantly recurring veins. Major Henry's success in organizing an effective company would be welcomed by our community, that would individually or collectively warrant its future.—*White Pine News.*

Mining at Columbia Hill.

The Nevada Transcript says: The Enreka Lake company, at Columbia Hill, commenced the construction of a long flume from a point on Spring creek near the road crossing leading by Hntler's to Priggin's mill, under the immediate supervision of A. H. Brigham, their efficient and energetic foreman, about one year ago. It is now completed over a mile in length. This property is known as the Consolidated flume, and is intended to wash all the aniferous gravel deposit extending from Cherokee to the backbone house and Lake City, and including all the old town site of Columbia Hill. This flume is one of the largest structures of the kind to be found in this part of the State, it being eight feet wide, five and three-eighths inches to 14 feet, requiring over 400,000 feet of 10-inch blocks to line it, although a portion is lined with rocks, which seem to run as well as the blocked portion. There were many miners who doubted the propriety of constructing a flume of such immense capacity on such a light grade; but this demonstrates the practicability of running this light sandy deposit on a light grade and with a comparatively small head of water, they only using from 1,500 to 2,000 inches, which moves a much larger quantity than was ever supposed. They are now washing a large portion of the deposit of tailings run from top ground into the ravine adjoining the side hill, which they are now sweeping into this enormous gateway for tailings. They now have a bank of 80 to 100 feet, which grows deeper and deeper as they continue into the hill, reaching to the depth of 250 feet above grade, before they get to the back of the ground. This mine covers an area of over 1,000 acres of ground, which it is estimated will take from 10 to 15 years to run off with the most approved appliances and machinery for working these immense deposits. This company is using 22 to 34-inch iron pipe, with a pressure of 150 feet, to which can be added, when necessary, 150 feet more, giving 300 feet pressure. They are also using one of Hoskins' largest size hydraulic giants, with an eight-inch nozzle. This is the largest one of these machines ever made. This machine, under the present pressure of 150 feet, will throw a stream of water through the eight-inch nozzle the distance of 350 feet, cutting the bank and rolling over and hoisting large stumps in the air like a boy would his bounding ball. It discharges from its present position 1,200 inches of water. The great quantity discharged will give the reader an idea of the tremendous power and force it has on any object that may come in its way.

The Simplest, Cheapest, Most Effective and Durable

Power Drill is the New

"CALIFORNIA" ROCK DRILL,

MANUFACTURED BY

HAWKINS & CANTRELL, San Francisco, Cal.,

AND SPECIALLY DESIGNED TO MEET THE REQUIREMENTS OF MINERS ON THE PACIFIC COAST

San Francisco Steam Pumps.

PREMIUM
AWARDED TO
W. C. WILCOX & CO.,
FOR BEST
STEAM PUMPS,
Wilcox's Patent.
1875.

AFTER ONE OF THE
MOST THOROUGH TRIALS

Ever Had in the United States,
BETWEEN COMPETITORS
—OF—

Best Established Reputation,
In which, at great expense, the different Steam
Pumps were tried under every test known
to experts, the Examining Committee
of the Tenth Industrial Fair of the
Mechanics' Institute have
awarded to us their

GOLD MEDAL
—FOR—
Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER
CONTRACT, guaranteeing their ability to
perform any specific work for which
steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

**FEEDING BOILERS, RAISING WATER
FROM WELLS; STEAMER AND
SHIP PUMPS, ETC.**

We would also call the attention of those
interested, to our Direct Acting Deep-Well
Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps
FOR HANDLING QUICKSILVER or heavy
liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we
ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

SOLE AGENT FOR THE PACIFIC
COAST FOR

**J. A. Fay & Co's Wood-
working Machinery,**

**Blake's Patent Steam
Pumps,**

**Tanite Co's Emery Wheels
and Machinery,**

**Fitchburg Machine Co's
Machinists' Tools,**

Sturtevant Exhaust Fan for Remov-
ing Shavings and Sawdust
from Machines.

**Sturtevant's Blowers and
Exhaust Fans,**

**J. A. Roebling's Sons Wire
Rope,**

**Pure Oak Tanned Leather
Belting,**

**Perin's French Band Saw
Blades,**

Planer Knives.

**Nathan & Dreyfus' Glass
Oilers, and Mill and
Mining Supplies
of all Kinds.**

BLAKE'S PATENT STEAM PUMP

Over 8,500 in Successful Use in the United
States.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.
To Suprs. of Quartz Mills and Mining Men generally:
We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburg Manufacturers
have been compelled to add largely to their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce SHOES AND DIES superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered,
flying from under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the largest
mills on the Pacific Coast, and all who have tried them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness on first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amalgam
by absence of iron dross, and a saving of
75 per cent. in freight. It takes 60 days to fill orders
from the manufactory East. Price 16 cents per
pound shipped at San Francisco. Terms liberal.

Tulloch's Automatic Ore Feeder.

WILL FEED WET OR DRY ORE.

LATEST IMPROVED

HENDY & COCHRANE'S ORE-FEEDER, FOR QUARTZ MILLS.

It is confidently believed to be the ne plus ultra of ore-feeders. One of these machines, on exhibition at the late Mechanics' fair, received the premium over all competing feeders. One was recently set up at Schnabel's mill in Newcastle, Placer county, Cal. It very soon showed itself to be the thing wanted; all other feeders under examination were at once rejected, and three more ordered for the same mill. We refer to the following mills using the Hendy & Cochrane feeders: St. Patrick, Pugh, Green, and Julian, Newcastle, Placer county. Keystone Con. M. Co., Lincoln and Oneida mill, Sutter Creek, Amador county. Tybo Con. M. Co., Nev. For description send for circular. J. HENDY, 32 Fremont Street, San Francisco, Cal., where it can be seen in operation. Also, manufacturer of Hendy's Improved Amalgamator and Concentrator and dealer in Quartz Mill Machinery and Machinists' Tools.

SAN FRANCISCO, SATURDAY, FEBRUARY, 19, 1876.

VOLUME XXXII
Number 8.

The Father of His Country.

Before another issue of the Press lies before the reader the Centennial year's anniversary of Washington's birth will have been celebrated with a spirit beyond that which the 22d of February has elicited during recent years. It is only natural that the Centennial year should awaken in us renewed appreciation of all the events which in any way contributed to the results we celebrate.

It is fitting that the birthday of Washington should be greeted this year with genuine thanksgiving. We care not whether the patriot impulse express itself in poem or oration; in noise of the salute or the harmony of anthems; in the measured pomp of the parade or the graceful variety of social reunion—each and all of these, if the spirit be right, may recall the debt of gratitude the nation owes to the father of his country.

History has formed its sober judgment of the character of Washington, and its own features can but illy conceal an expression of enthusiasm at the contemplation of his glorious deeds gloriously achieved. Oratory has adorned its roundest periods with his high sounding name. Patriotism has kindled in a world of hearts and nations have gained new life and liberties with the watchword taught the world by Washington. It would be idle to recite the glories of his life. The world knows them. Every language of civilization speaks his praise. Every generation of men will early learn his beneficent accomplishments, so long as eloquent words are expressive of noble thoughts.

But there are a few avenues through which it may be of vital value to-day to draw light from a memory of Washington. It matters not though the light dazzle eyes which have grown accustomed to the darkness begotten of the events of recent years. It may expand the contracted pupil with which the national eye has learned to look upon truth, virtue and disinterested patriotism to let a bright, sharp flash of early nobility and manhood pierce it. It may awaken the sluggish national conscience, seared by a blast of revelation of every grade of evil doing, in public and in private station, to contemplate a life of disinterested goodness, of parity and of truth.

It is difficult to go back to the time of Washington. Let us bring Washington to our own. What do we see? Shall we call him Washington-Tweed, plundering a metropolis and buying legislators hand and soul? Shall we call him Credit Mobilier Washington, convert a national enterprise into a scheme for robbery? Shall we call him the Washington of Rings, encircling a nation and leading those nearest to the chief-magistrate into deeds meriting criminal indictments? Or shall we call him the Washington of Corporations and Monopolies, paralyzing the industries of the country by despotic exactions and making the springs of wealth and prosperity tributary to powers ostensibly arranged to be their servants? Shall we call our politicians by the name of Washington? Washington buying a majority of a legislature that he may be a Senator! Washington enchainning the conscience of the civil service of the nation with the alternate of support or surrender! Shall we call our spiritual and moral leaders Washington, when the highest of them cannot clear his skirts, even with all the appliances of modern justice? Shall we call our private citizens Washingtons, when the air is filled with the reports of embrozzlements, defalcations and crimes?

It is not a pleasant contrast which is afforded by holding the honored name close to the plentiful instances of present dishonor. But it is well to make the contrast, nevertheless. As we approach the thickest darkness the light brighter shines. Perhaps we could not honor our hero better than to note that thus, after a century's existence of the nation he founded, his name shines so like a star upon the night of our ill doing. But a star is a double symbol. It recalls the light which has departed and it heralds the light which is approaching. Thus let the memory of Washington be our star on this Centennial year. Let it usher in the day which shall rival the light which attended his uprising. As by his arm and councils he freed a nation from the power of kingly oppression,

so now let his memory lead us through this era of official corruption and social demoralization. Thus will his deeds live after him. Thus will arise a generation fitter to maintain his fame and speak his praises.

An English Journal on the Hayden Survey.

We have had occasion to make liberal extracts from Prof. Hayden's report of his

noticing the list of publications of the United States Geological Survey under the direction of Professor Hayden, testifies in a very flattering manner to the value of the work:

"We feel it our duty to call attention to the truly magnificent character of the survey now being executed on behalf of the Government of the United States. Not merely the geology, but the mineralogy, botany, zoology, meteorology, ethnology and antiquities of the whole

Vertical Wood Boring Machine.

We give on this page an illustration of an improved vertical wood boring machine, manufactured by Bentel, Margadant & Co., of Hamilton, Ohio. The machine has a frame strongly constructed of a hollow column, heavily braced by I-shaped web ribs, and a broad base, well calculated to resist jarring and trembling. The table is also strongly made, and is adjustable to any angle or position. It can be raised and lowered by means of a rack and pinion, turned on its axis, and can be tightened at any length by a simple turn of the handle, which closes a long split bearing. The table proper can be inclined at different angles, and the upper part may be moved out or in, revolved, and adjusted. A cone pulley of three steps enables the operator to run the machine at three different speeds, for large, medium or small sized machine augers. It has a commodious self-returning treadle, which requires very little power to bring the auger bits to the necessary depth.

Holes can be bored at any angle, from one-eighth of an inch to three inches diameter, and from one-quarter of an inch to 12 inches depth. An adjusting stop on the connecting rod gauges the depth of the hole. The rests on the table can be adjusted for straight, square, oval, circular and bent work. The idler pulleys (which are frequently a source of trouble in such machines) do not need re-adjusting for different heights of the countershaft from the machine. The manufacturers direct special attention to the facility with which a number of holes, with variations of angle, can be accurately bored. In the slots of the radius brace one or two stops can be inserted in such a way that the table can be swiveled from a horizontal plane to either side; and, as the table slides forward and backward, and can be turned on its axis, it is obvious that, in a piece of timber, a number of holes can be bored which differ in angle and place, without moving the work about. The machine is adapted for boring short as well as long pieces of material, and will do the work, it is claimed, with great ease and rapidity. The countershaft with cone pulley, as shown in the engraving, may be set on the same floor with the machine, or attached to the ceiling, so that the belt may pass from either side, in an inclined direction or perpendicularly. The tight and loose pulleys are of nine inches diameter, three and a half inch face, and should make 250 revolutions per minute.

THE AMAZON AND GLASGOW MINES.—New machinery for the Amazon and Glasgow mines has been ordered by telegraph, and within ten days it will be upon the ground, consisting of a fine eight-inch Blake pump, boiler, etc. A full force of men are employed in grading for the foundation and enlarging the size of the main building to meet the requirements of increased motive power. The body of water recently struck comes principally from the north drift, where the vein widened very perceptibly and up to the last work done was daily improving in appearance. On the evening of the 8th, the water had increased so that all underground working had to be suspended, the small donkey engine being unable to keep it down. The company do not by any means feel discouraged at this; on the contrary, they deem this unusual flow of water a good indication that the large vein from which it comes contains a larger percentage of precious metals than before shown, and when the new pumping machinery is in place and at work we hope their expectations may be realized.—*Lyon County Times*.

A NEW LEAD DISCOVERED.—J. C. Harris and J. C. Phillips discovered a new lead in Winnemucca mountain this week which promises to be valuable. The croppings assay \$87 per ton in silver, and are three feet wide. The discoverers have located 1,500 feet of the ledge in accordance with the United States mining laws.—*Silver State*.

NEW STRIKE.—Intelligence has just reached us that a rich and extensive strike has been made in the third level of the Paymaster mine at Ward district. We understand that it is the first ore that has been found in that particular locality of the mine. The Paymaster is getting to be a "way up" mine.—*White Pine News*.

VERTICAL WOOD-BORING MACHINE.

surveys through Colorado and adjoining Territories, and we have reason to believe that the interesting descriptions and graphic engravings of the wonderful scenery of that section of the country, while they have served to embellish the pages of the Press, have been well received by our readers. We are glad to know that the labors of the Professor are appreciated abroad as well as at home. In the January number of the *Quarterly Journal of Science*, published in London, and edited by Professor William Crookes, F. R. S., the editor, after

Union are being carefully explored. Will the day never come when a similar survey will be made of the still wider and more varied regions included within the British Empire? It would be a glorious contribution to science and a worthy bequest to posterity."

In the western portion of Placer county roses are blooming, wild flowers appearing on the plains, oranges ripening and grain a foot high, while in the middle and eastern end the snow is from 10 to 30 feet deep, and the mercury frequently drops below zero.

CORRESPONDENCE.

More About Straw Burning Engines.

EDITORS PRESS:—I was considerably interested and amused by reading an article in your last issue, having the above title, and signed J. W. Riley. This gentleman appears to thoroughly understand his subject, in so far at least as his own observations have gone; beyond that, and what may be doing in other parts of the State in regard to this species of industry, we are left in blank.

But if you will allow me, Sirs, I will add a few supplementary remarks to Mr. Riley's article, which may not be altogether out of place, or displeasing to the parties mentioned. We shall all agree in saying that all honor is due Mr. Rice for the energetic measures that, in conjunction with others, he has taken to bring to a successful issue his idea of an engine that shall burn straw alone for fuel, and yet lose not one whit of its power or usefulness.

But we are naturally led to inquire, is Mr. Rice alone in the field, or are there others that deserve honorable mention at our hands? I think there are, and first and foremost among the claimants stands prominently forward the name of

Mr. Enwright, of San Jose.

It is nearly ten years ago, (if my memory of dates is correct,) since the idea occurred to Mr. Enwright that it would be just as feasible to use steam power with threshing machines as to use steam power in a sawmill, or elsewhere, and thus keep step with other parts of the world, where they were already in active operation; whereupon, without adequate means, without proper tools, with the whole voice of the community against him, does he at once set to work to build his engine. That it would never do, that it would set everything on fire, that farmers would never allow it inside their fences, that it would be the foolish fellow's ruin, of course every one agreed to, but in spite of all this, Mr. Enwright built his engine, and after a good deal of persuasion, a farmer allowed him to try it with his grain, the builder being responsible for the damage it might do.

The Result.

Of course is well known; horse-powers were at a discount at once, and those that had laughed the loudest, now were the wisest, who had always known it would prove a good thing. Since that time Mr. Enwright has built a large number of engines, which compare favorably with others, either imported or those of home manufacture. Of course they all burned wood. Within the last two years this enterprising gentleman has turned his attention to straw burning engines, and last year a number of them were doing very good work in the harvest field. As he drove out the horse-powers with his wood burning engines, so now he threatens to drive out their turn by his straw burners, and he is in a fair way to do it. For simplicity, durability and strength, I can safely say, from personal observation, that they are equal to anything of their kind that has ever gotten up steam in this State. The boiler has return flues, the straw being fed to the furnace by hand, without the intervention of any machinery whatever.

Brown Brothers of Salinas.

Then there is a firm of builders that has recently started at Salinas, in the manufacture of engines that are to burn straw. I refer to the Brown Bros. These gentlemen, within the last few years, left their home in Australia, and have settled down in this State, as offering the best advantages and the surest returns for capital invested of any country they have ever seen. They have bought extensive grounds at Salinas, and erected a large two-story building, where they mold their own castings and do their own work generally. Already they have built some eight or 10 straw burning engines, which have given eminent satisfaction; and so confident are they that ultimately they will be used to the exclusion of all others, that this year will witness another hatch of them turned out of their erecting shop, they being eagerly bought up by the farmers and others in their vicinity. A firm of

Santa Cruz Builders

Tried their maiden hand last year on this class of industry, and though not so successful as others, they will do better in the future and learn wisdom from past failures.

At Watsonville

We have Mr. McLean throwing open his large shop for our inspection, and although this gentleman has not built any of these engines as yet—contending himself with remodeling some and repairing others, yet it is the nucleus for much larger things in Pajaro valley in the immediate future; many others, too, in different parts of the State, are expending time and money in the same direction. Let a want once be felt and we may safely let our American genius alone for quickly supplying that want.

Mr. Riley informs us that an English firm has sent one of their straw burning engine to this coast. Of course we are very much obliged,

but California presents her best compliments to England, with many thanks, but thinks she can supply, through the means indicated, her own children in this direction for many years to come.

That in the construction of these engines there are difficulties to be encountered, of course no one questions, but that these difficulties will be eventually overcome no one doubts, and it is the truest wisdom to frankly acknowledge them, and set about their remedy, rather than gloss them over, and assert that everything runs smooth—that there is nothing left to be further desired. Of course there is an enormous pile of straw burned during a day's run, and that in its turn must make an enormous quantity of clinkers and cinders, and how most readily to get rid of these is one of the difficult problems that our engineers are required to solve. The burnt straw is naturally light and feathery, and the strong draft sucks up these particles against the flue sheet, but being too long for most of it to pass through the flues, it commences to form a compact mass over their mouths, and very shortly the whole flue sheet will be completely covered with a mass of stuff two or three inches thick, thereby stopping all draft until it is removed, sometimes causing considerable inconvenience. That this and other obstacles can be removed I am quite confident of, and that too in a very simple manner, but the modus operandi I must leave until next time.

C. Z. SANDERS.

San Francisco, Feb. 10th, 1876.

Placer Mines in Kern County.

The *Stock Report* gives a brilliant account of the new placer mines being opened out on the Kern river. In a late issue it says:

We were fortunate enough yesterday to enjoy a long conversation with a mining engineer of experience, who has just returned from that section, and who speaks most flatteringly of the prospects of the new placer mines. He showed us the results of some dozen or more pans which he had washed, varying from about 10 cents to a dollar according to the depth from which they were taken, but in no case, not even in that of a pan washed from the very grass roots, failing to show a color. Of course nearer the bedrock it is very much richer. From the conversation of this gentleman we gathered a good idea of the extent of the auriferous deposit. The company owns a large quantity of land extending from the mountains down to the river bank, 250 acres of which is known to consist of rich gravel. Of this much lies in the old river bed, which is 150 yards wide and from 20 to 30 yards deep. This presents the most favorable possible condition for hydraulic mining, as the gravel is exceptionally clean, the bedrock hard granite, worn into a trough-like shape by the former action of water, and there is a complete immunity from all unfavorable conditions, such as clay or cement in the gravel, tree stumps or large boulders. There will therefore be no waste of gold, and all that the gravel contains can be taken out. Setting the yield at the lowest figure—50 cents per cubic yard—we have a gross yield of \$50,000 per acre, and 75 such acres give a total yield of \$3,750,000, which must be acknowledged to be very comfortable and satisfying figures. The cost to work the ground may be estimated at one cent per yard, or \$1,000 per acre, leaving the satisfactory net product for 75 acres of \$3,675,000, and the probable contents of the entire auriferous portion may be proximately stated at \$6,000,000. The washing capacity of the water supply will be about 7,000 yards, or \$3-750 per day, at the cost of little more than \$50. In the above estimate the value of the ground is taken at an average of 50 cents per yard for perfect safety, but prospecting shows it to yield all the way from 50 cents to \$150 per cubic yard, according to distance from the bedrock. The gravel being all water deposit, is evenly distributed that its value at different depths can be very readily calculated from a few prospects, and owing to the favorable nature of the ground the expenses of working can be as easily computed. The principal outlay will be the water supply, which has to be brought a distance of about 10 miles. The ditch is at present in process of construction, and half its distance will be flume construction, requiring about 800,000 feet of lumber. The entire expense of bringing in water, the supply of which will last the year round, and of opening the ground, will be about \$50,000. The company is now fully organized and work will be pushed forward briskly.

THE PHENICIAN BONANZA.—George F. Dinsmore, of this city, sent a small lot of rock from the Phenician lode, Barker Hill district, to Joseph Barnett, at Salt Lake, who is a joint owner in the mine. Mr. Barnett had an assay made of the ore, the certificate of which was received in this city this morning. Following is the result: Silver per ton, \$2,119.26; gold per ton, \$301.46; total assay value, \$2,420.72 per ton. This mine is situated about 35 miles south of Anetin, and has lain unworked for some time owing to the remoteness of its location, but it has long been known as a valuable property. The existence of such mines as this in our immediate vicinity, yet too far distant from the railroad to admit of cheap working, is a strong argument in favor of the speedy construction of the Austin and Battle Mountain railroad, the completion of which would be the means of opening up a large number of such bonanzas as the Phenician. —Austin Reville.

Motive Power for the Centennial.

The monster engines to furnish motive power for the Centennial Exposition are being erected in Machinery hall. They were built at Providence, R. I., under a contract made with Geo. H. Corliss, of that city. The engines are what is known as "beam engines" of the Corliss pattern, with all the latest improvements, and nominally of 700 horse-power each, or 1,500 horse-power in both, though this can be increased even to 2,500 horse-power should occasion require. The cylinders are 40 inches in diameter, with 10 feet stroke. The engines are provided with air pumps and condensing apparatus, and are intended to work with 25 to 30 pounds of steam, according to the requirements of the exhibition.

The gear fly wheel is 30 feet in diameter, two feet across its face, and when completed will weigh 56 tons. And as one looks on it at the works, it is easy to believe that it is the heaviest cast wheel ever made, as indeed it is. It has 216 teeth, and these are to be finished with such degree of accuracy, such perfection of nicety, that though the wheel is to make 36 revolutions per minute, it is confidently expected it will run noiselessly. The crank shaft is 19 inches in diameter and 12 feet long, of best hammered iron. The "bearings" for this shaft are 18 inches in diameter, 27 inches in length. The cranks which, seen alone, seem to be enormous, are of gun metal, highly polished, and weigh over five tons each. The walking beams are of new design, and are nine feet wide in the center, 27 feet long, and weigh 11 tons each. These are cast solid, while the gear fly wheel is cast in sections. The connecting rods are about 24 feet long, and are made of horse shoes, or to be literally correct, of horse shoe scrap iron, that being considered the best iron that can be obtained. About 9,600 horse shoes were used in making the connecting rods. The piston rods are of steel, 6½ inches in diameter, and the velocity of the pistons will be 720 feet per minute. The large gear with which the gear fly wheel connects is 10 feet in diameter, and is a solid casting weighing 17,000 pounds. The height of the engine from the main floor to the top of the walking beam at its highest pitch will be 39 feet, and every part of it will be accessible by means of iron staircases and balconies, which are so designed as to contribute largely to the embellishment of the whole. The weight of the engine and everything connected with it is 700 tons. The engine will be placed in the transept, in the center of the hall, directly facing the main side entrance. The building here is 70 feet from the floor to the top of the ventilator, thus giving ample height for the working of the engine. The gear fly wheel will connect, underneath the floor, with the main shaft, which will be 252 feet long and run cross-wise of the building. The main belts, instead of being an eye-sore and in the way, as is too often the case, will pass through the hall in out-of-the-way places, and be enclosed in glass apartments 8½ feet in size, so as to make a proper exhibit of the belts.

The boiler house is now being erected a short distance from the transept and 36 feet from the main building. In this there will be 20 of the Corliss upright boilers, of 70 horse-power each, connecting with the engines by means of pipes underneath the floor 320 feet long and 18 inches in diameter, of wrought iron double riveted.

Consolidated Virginia Dividends.

Stockholders in the Consolidated Virginia mining company received their usual dividend of \$10 per share last week. The company first commenced paying dividends in May, 1874, at the rate of \$3 per share. In March, 1875, the dividends were increased to \$10 per share, and this is the twelfth consecutive dividend of that amount that has been paid. Following is a list of these monthly disbursements:

Per Share.	Amount.
May, 1874.....	\$3
June.....	3
July.....	3
August.....	3
September.....	3
October.....	3
November.....	3
December.....	3
January, 1875.....	3
February.....	3
March.....	10
April.....	10
May.....	10
June.....	10
July.....	10
August.....	10
September.....	10
October.....	10
November.....	10
December.....	10
January, 1876.....	10
February.....	10
Totals.....	\$150

As the dividends represent 50 per cent. of the yield, it follows that the product of the mine for the last 22 months has been upwards of \$30,000,000. The monthly yield now is close upon \$2,000,000, and unless some adverse circumstances should occur, will be maintained at that figure throughout the remainder of the year.

QUICKSILVER.—The bad condition of the roads has so interfered with the shipments of quicksilver from the Redington mine that about 1,000 flasks, a month's production, has now accumulated. During ten months of last year the mine yielded 8,080 flasks of quicksilver, the bulk of which passed into the hands of Flood & O'Brien under contract.

From the Julian District.

A correspondent of the San Diego *World* writes from Julian as follows:

Along the mineral belt diverging toward Banner are the Ella mines, owned and being worked by John Murray, Atkinson & Co., the Kentuck, owned by and under the supervision of Messrs. Bailey & Brawley, the Madden being worked under a lease by Cooper, Clyde & Co. Each of these mines are taking out first class ore. These mines, in days past, turned out many thousands of dollars, and must ultimately develop into rich and extensive mines.

Still further east are the Ready Relief and Hubbard mines, the former owned by Neyhart & Co., the latter by Messrs. Woodruff, Thurman and others, both being on the same veins and adjoining each other. These mines have an inexhaustible body of ore to take out.

The Ready Relief company have a fine 10-stamp mill on the mine which is kept busy. The Hubbard company are erecting a mill on their mine, so I am reliably informed.

The developments made in the Helvetia and Tom Scott mines, which has demonstrated beyond question that the mines at Julian are not only extensive and permanent, but increase both in size and richness as they acquire depth, has stimulated the owners of numerous other mines which have, for the past two or three years, been lying in a state of suspension, to resume work, and there is at the present time more work being done on this class of mines, and prospecting for others, than at any time previous in the history of the district; and it is the opinion of your correspondent that these efforts will result in the development of some first class mines.

New Mining District.

A correspondent of the Winnemucca (Nevada) *Silver State*, writes from Oresana concerning a new mining district as follows: Some mines were discovered near here some time since, which are likely to prove of considerable importance. The discovery in question was accidentally made last October by John O'Kane of Big Meadows, while hunting horses in the extreme southern end of Antelope mountains. Shortly afterwards O'Kane, J. B. Brown and M. Guerin went to prospect the find, and while doing so discovered several veins of carbonate and galena ores. The former assay from \$100 to \$260, and the latter from \$200 to \$500 per ton in silver. The veins run parallel with each other and are from 20 to 40 feet apart. The first or most eastern vein of the series divides a granite from a slate formation and all of them dip east. A good many locations have been made, but, as Methodist ministers say at revivals, there is room for more, and an inviting field is open to prospectors. The owners are now going to work to develop these mines to some extent, and have now on the ground everything ready for a starter. Several mining experts have visited the district lately and all seemed to be favorably impressed with the prospect. Some parties offered to bond the mines for \$29,000, but the owners prefer prospecting them until their extent and probable value is more fully ascertained. These mines are located near San Jacinto district, eight miles southwest from the Humboldt house on the Central Pacific railroad.

MANUFACTURE OF METALLIC LIFEBOATS.—A new industry has been inaugurated in San Francisco. The well known machinist, Mr. J. F. Penny, is now engaged in building four metallic lifeboats for one of the Goodhall, Nelson & Perkins steamers. Two of them are 26 feet long. The larger ones are 28 feet long, with a breadth of eight feet, and a depth of three feet three inches, and are capable of carrying 50 or 60 persons in a heavy sea. The gunwales, benches, stern post, stem, keel, etc., are of angle pine, Oregon pine and Eastern oak. Fore and aft are large air-tight compartments. The bottoms are of galvanized iron an eighth of an inch thick, brought from Pittsburg. It is believed that this is the only metallic lifeboat factory anywhere along the Pacific shores of the continent. It is much cheaper to bring the iron overland by rail than it is to purchase the boats at New York and have them shipped either by rail or steamer. They make no widdy freight, and rough handling damages them. This being the case, no reason exists why a great industry of this character might not be gradually built up at a port like San Francisco, where ships from every quarter of the globe are constantly arriving and departing.

RESPONSIBILITY FOR NOT RUNNING TRAINS ON TIME.—The responsibility of railway companies for damages arising from not keeping time with trains according to published time hills, has been settled in England by a decision rendered by a London superior court in a recent case. A Mr. LeBlanc sued the London and Northwestern railway company for the cost of a special train from Leeds to Scarborough, which the plaintiff had ordered in consequence of his being brought from Liverpool to Leeds too late for the ordinary train from Leeds to Scarborough. The case came up in a county court, and was decided in favor of the plaintiff, the judge ordering the London and Northwestern company to pay the costs of the special train. The railway company appealed in the case to the superior court, where the points raised were argued by able counsel. The decision of the lower court was affirmed.

SULPHUR MINE SOLD.—Theodore Hale has sold his sulphur mine at Inferno to parties in this city.

MECHANICAL PROGRESS.

Combined Iron and Steel—New and Important Invention.

The uniting of iron and steel by welding is nothing new. It has long been more or less perfectly done by the use of various fluxes, but when well done it has been at the expense of much labor and cost. To illustrate this we need but instance the outfitting of a boot and shoe manufacturers, etc. These are made by welding, a few inches at a time, a narrow strip of steel on to one side of an iron bar, by the tedious process of a forge fire and hand hammer. The billet thus prepared is heated to a "cherry red" and drawn down to a thin band about two inches wide. This operation is costly and the product correspondingly high in price, bringing several hundred dollars per ton more than cast steel. The combination of the metals in this manner is not only costly and laborious but circumscribed within very narrow limits.

Efforts were also made a few years since to weld steel tops to iron rails by means of powerful rolling machinery, but so loosely was the steel held to the iron that the two metals soon separated and became quite as dangerous as the primitive plate rail which so often turned up as a "snake's head" and went crashing through the cars to the almost sure destruction of life. But we now hear of a

New Mode of Welding Steel to Iron. Recently invented by Mr. Eldridge Wheeler, of Philadelphia, which promises to effect quite a revolution in the economical and effective mode of the process. The merits of the invention are undoubtedly large, and command themselves at once to the intelligent mechanic and engineer.

Our own government has recognized its value, and the Chief of Ordnances at Washington has been appointed to give this matter a thorough investigation. Bismarck, who has already been informed with regard to it, has detailed one of his most experienced engineers to visit Philadelphia for a similar purpose.

The principle of this process rests in the fact that the only practicable way to make a business of uniting iron and steel is to bring them to a welding heat in one "pile" and simultaneously, and to then manipulate them by rotary motion. The difficulty which has hitherto been considered insurmountable, is that steel exposed to the high temperature requisite to bring iron to a welding heat is "burnt" or essentially injured. "Fluxes" but imperfectly and impartially obviate this, and beside the uncertainty of result, their use involves in large works a tediousness and difficulty of operation utterly incompatible with economy.

By this process a combination between steel and iron is as easily effected as between iron and iron by the ordinary method, and indeed with the same appliances, by the simple means of entirely and completely protecting the steel with iron from the oxidizing and decarburizing effects of excessive heat. In short, the steel is put into an iron case made as nearly air-tight as possible, and thus enclosed it is no more liable to be injured or "burnt" than is steel when melted in a black lead crucible.

Artillery officers who have examined this new invention are enthusiastic over it, for the great benefit that will be derived therefrom in the more thorough construction of cannons. Small arms will also receive an almost equal advantage, as both may now be practically steel lined within the bore. It is also equally applicable to wagon tires and car wheels, and to axles. In fact there is no combination of the two metals which cannot be more easily and accurately effected by this than by the old process, while its applications are so many, and of such value, that it would be impossible to give a full and intelligent summary of them with our limited space.

A cotemporary sums them up, under three heads, as follows: First, the reduction of steel into an iron-coated steel plate, or bar, in which case steel preponderates; second, the production of steel-centered iron, where iron is the principal metal used; and third, combination proper, in which the steel is so proportioned and placed as to endure wear and support strain. An important feature of this invention is that scrap steel of any kind, Bessemer rail ends, etc., can be utilized. Being "piled" as required and enclosed in an iron crucible, the steel, protected by the iron, can be heated to a semi-molten state, and when softened the weld to itself and to the surrounding iron is positive. No steam hammer is required to work the mass, but its reduction to any particular shape desired is effected with ordinary rolls, and with the same facility and speed as a pile of iron.

This iron-coated steel is especially adapted to subsequent forging, as the thin shell of iron continues to effectually protect the steel from injury by heat, and in the finished article made therefrom, as a horse shoe, the steel can be hardened without danger in use, the iron coating preventing fracture. If desirable, the iron can be so proportioned as to be in the bar, plate, or sheet but an extremely thin coating, or even an almost imperceptible film, easily planed, turned, or ground off, leaving a smooth surface.

We shall make more full reference, next week, to the advantages which this invention possesses over all others in the manufacture of cannon and small arms.

Artificial Spiegeleisen.

A discovery of much importance to iron manufacturers has recently been made by Dr. Etheridge, which consists in the artificial production of spiegeleisen, one of the indispensable ingredients in the manufacture of Bessemer steel. Hitherto all the spiegeleisen used by our manufacturers has been imported either from Germany or England, because it was supposed that among all our minerals, the peculiar species composed of manganese and iron naturally combined, and called manganiferous iron ore, the technical name for which is "spathio iron ore," did not exist here. And very likely the peculiar combination, so plenty in Germany, Spain and other parts of Europe, does not exist here; but we have limitless quantities of both in a separate state, and Dr. Etheridge's valuable invention consists of a process by which the two can be combined and made even more effective than the natural ore. The essential ingredient in the spiegeleisen is the carbon, which, being liberated, unites with the iron to make steel. The principal feature in Dr. Etheridge's invention is the use of a closed chamber, in which to flux iron, carbon and manganese. The exceedingly great refractiveness of manganese is what has hitherto foiled all attempts to make spiegeleisen from the American ores in cupolas. Placed in a closed chamber, these three ingredients can be subjected to any degree of heat desired. When the fusion point of manganese is reached, the carbon, having no chance to escape through oxidation (because air is excluded), becomes incorporated with manganese and iron, and the result must be spiegeleisen. The kind of spiegeleisen produced can be made to vary as desired in its percentages of carbon and manganese. The latter forms five different chemical combinations with carbon, varying from five to 36 per cent. By taking advantage of this fact, steel makers can make their spiegeleisen so rich in carbon and manganese that it can be made to go four and even six times as far, bulk for bulk, as imported spiegeleisen.

It is estimated that \$100 per day can be saved to each Bessemer plant in the manipulation alone of this improved spiegeleisen. So much less bulk being required to be fluxed, this economy in fuel and manual labor will be prominently observant to steel makers.

The most important desideratum of this invention is the enabling American steel makers to manufacture their own spiegeleisen on their own grounds from the separate ingredients, thus freeing them from their abject dependence on foreign markets separated from them by 3,000 miles of water.

SOLID CASTINGS.—A method has been devised by an English inventor, by which, in the running of steel and other metals, in a molten state, into ingots or other molds, a much greater degree of solidity, and consequently of strength and endurance, is insured. In this production of ingots or castings by this means, an air-tight cover is fixed on the top of the mold, with an aperture for running the metal into the same, either through this cover or other convenient point; and connected with this cover is a tube or pipe, with stop valve communicating with a vacuum chamber. At the proper time the stop valve is opened, and a communication is established between the mold and the vacuum chamber, by which means the air in the mold and the vapor arising from the molten metal are instantly drawn away; or the mold and box are fixed in an air-tight chamber, and the air end vapor then withdrawn in the manner described. The vacuum may, in this arrangement, be established and maintained by an air pump or other ordinary; and the method is both effective and free from complication.

A NOVELTY IN STEEL MANUFACTURE.—Letters patent have been granted to Messrs. Thomas A. Freeston, steel works manager, and George Ellinor and John Harrison, chemists of Sheffield, England, for improvements in the manufacture of iron and steel. The patent is said to be a very valuable one, and has for its object the purification of iron and steel. The process consists in the use of certain materials or compounds for the removal and elimination of sulphur, phosphorus, antimony, arsenic and copper from iron and steel, whether in the crude or advanced stage of manufacture. The benefits obtained from the invention, among others, are the production of a greater amount of pure iron or steel from a given quantity of raw material. The making of a superior class of iron or steel out of cupolas or blast furnaces and shortening the present circuitous mode of making good steel for rails is claimed; and it is even alleged that tool steel may be made from the Bessemer material by means of this process. The precise nature of the materials or chemical compounds used to effect the purposes claimed by the inventors are, as a matter of course, a secret.

BESSEMER PROCESS DEVELOPMENTS.—In a review of the iron trade for 1874 Hupfeld remarks that in improvements in the manufacture of iron and steel, quantitative progress only has been made for the most part, the best example of which is in North America, where for instance, at the works of Troy, New York, and the Cambria iron works, Pennsylvania, an average of 40 to 45 charges is made in 24 hours, two converters producing close on 1,000,000 wt. a year. On the Continent and in England the old Austro-Swedish method of direct working from the blast furnace is much in vogue, with the intent to lower the cost of pro-

duction, and so make head against competition (Neuberg, Turrach, Hoft, Reschitz, Dortmund, Sraing, Crusot.) Steel works without blast furnaces of their own endeavor to reduce the expense of re-melting by working up scrap with pig, at a high temperature. At Ternitz and Teplitz, in a combination of the Bessemer and Martin process, 60 per cent. of the charge is scrap. The scrap is thrown melted or cold into the converter with heated pig rich in silicon; with charcoal pig poor in silicon they are heated in the Martin furnace.—*English Mechanic.*

BESSEMER STEEL.—The success which is attending the attempts to substitute Bessemer for iron in many branches of manufacturing and construction, is full of promise for this industry. We have hardly done wondering at one achievement before we hear of another. Where the first rude and crude attempts to use it proved failures later experiments have proved successful. We have already informed our readers of the successful manufacture at Troy of horse shoes and nails from Bessemer. The shoes, it is claimed, are lighter and wear longer and more even than those of iron, while the cost is not much in excess of iron. The nails, it is asserted, can be driven through oak planks and clinched.

SCIENTIFIC PROGRESS.

Measuring Earthquakes on Mt. Vesuvius

The observatory at Mt. Vesuvius, presided over by Prof. Palmieri, is situated on a spur of rock on the side of the mountain, close to the Hermitage or half-way house. The delicate instruments used for registering the direction and force of earthquakes shocks are in the second story of the house, but are built on solid piers of stone reaching to the earth. The instrument for the automatic registration of vertical shocks is a fine metallic point, suspended by a coil of wire just over the surface of a cup of mercury. The slightest upward motion of the earth carries the mercury up to the wire, completing a galvanic circuit which instantly stops a clock and rings a bell to notify the observer to reset the apparatus and observe future phenomena. To measure the intensity of vertical shocks, small magnets are suspended over a cup of iron filings by means of coils of wire of different strengths. When a vertical shock occurs some of these magnets dip into the iron filings, and to one of these a light index is attached for measuring the intensity of the shock. For horizontal shocks the registering apparatus consists of U shaped glass tubes, partially filled with mercury, and set to the four cardinal points. A small weight rests on the mercury and is attached to a silk fiber, which runs over an ivory pulley and has a counterpoise at the other end. On each pulley there is an index and circular scale to mark the angle through which it turns. A horizontal shock causes the mercury to rise in the tubes or tubes corresponding to the direction from which it comes, the weight is raised and the pulley marks, by means of the index and the angle through which it has turned. At the same time the mercury in rising completes a galvanic circuit which stops a clock and rings a bell. The galvanic current from either registering apparatus also starts another clock, the pendulum of which has hitherto been held out of perpendicular, and this clock allows a roll of paper to be unwound, on which, by means of electricity, a pencil traces the movement of future shocks, the spaces between the markings indicating the time elapsing between the shocks. There is other apparatus in the observatory for measuring atmospheric electricity and for similar purposes, and presiding over all this delicate mechanism is Prof. Palmieri, who devotes all his time to the study of the great forces concentrated in his little world—Mt. Vesuvius.—*Philadelphia Ledger.*

A most interesting demonstration of the tremendous force of electricity was incidentally made in the course of an experiment upon a tube three-eighths of an inch exterior and one-eighth interior diameter, which could stand a pressure of at least 200 atmospheres to the square inch; this tube was fourteen inches long and bent at a right angle. A very large electric flash being sent through the tube it was split by the first discharge and the pieces thrown to a distance of several feet. The inner surface of the tube was, in fact, completely pulverized, so though it had been struck by a hammer. Mr. Reynolds estimates that the pressure must have been more than 1,000 atmospheres.

HOW ELECTRICITY SPLITS TREES.—The theory that the splitting of the trunks of trees by lightning is the result of the sudden evaporation of the liquids contained within them, has received much confirmation from experiments made by Osborn Reynolds, who succeeded in splitting small sticks of wood by passing the electric spark through them after they had been impregnated with water. He also burst small glass tubes which were filled with water, although the same tubes when empty allowed the electric spark to jump through them without in the least disturbing them.

IS IT THE ROQ?—Various accounts have lately been received of the appearance of an enormous rapacious bird in the interior of New Guinea, which has been called *Harpypopsis Nova Guinea*. May it not be the "roq" of the Arabian nights?

Sound Waves and Safety Lamps.

Twenty-two large explosions have taken place in English coal mines since the year 1866. Among these seventeen took place at the moment of the firing of a blast at a distance. Galloway conceived from this the suspicion that a violent sound waves might be capable of pushing the flame through the wire gauze of the safety lamp and thus ignite the inflammable gas around. It was known that when explosive gases are drawn through a wire gauze with a velocity of ten to twelve feet per second the flame penetrates and ignites them; but it was not known that a sound wave would do the same thing, and this is what Galloway has proved by experiment. He placed a safety lamp in an explosive mixture and fired a pistol at a distance of twenty feet, or ignited a box filled with a mixture of coal gas and oxygen. In either case a large flame was projected through the wire gauze out of the safety lamp and ignited the surrounding gas. He found no difference when the gas was separated from the air by means of a thin membrane, which would not permit air currents to pass, but only transmit the sound wave. This experiment was varied by transmitting the sound wave through a tube twenty feet long, and of which the axis was directed toward the safety lamp; closing this tube with an elastic membrane made no difference whatever. He therefore came to the conclusion that a blast in a coal mine may make all the safety lamps useless, while it explains the fact that an explosion in one part of a mine is often immediately followed by another explosion at a distant point.—*The Laboratory.*

CHEMICAL ACTION OF WATER ON IRON.—As an evidence that iron will not oxidize in pure water, take a piece of clear ice, melt it and heat to boiling; after boiling a short time, to free it of air, pour it into a small vial containing some pieces of bright iron wire. This vial must be quite full and tightly stoppered. Place a similar piece of wire in an open vessel and partially cover it with water. Set both vessels aside for a few days, when it will be found that the wire in the former is still bright, while that in the latter is rusted. This experiment shows that it is the oxygen of the air, and not that chemically combined to form water, which acts upon iron; moreover, experiment has shown that neither dry oxygen nor dry carbonic acid will attack iron. To produce the action of common oxidation upon iron the oxygen must be combined with nitrogen, as it exists in the atmosphere, and in all potable water.

MOTIVE POWER FROM ARTIFICIAL LIGHT.—We recently described at considerable length a mode of deriving motive power from sunlight. At a recent soiree of the President of the Royal Society, Dr. Crookes exhibited an extremely sensitive radiometer, with which he was enabled to perform the novel experiment of producing mechanical motion in vacuo through the agency of the rays proceeding from a candle flame at some distance from the apparatus. The following is a brief description of this ingenious device: It consists of a glass stem supporting a four-bladed windmill carrying four discs, one at each extremity of the four slender glass rays. These work horizontally and are supported by a steel point on a small topaz. The apparatus is placed in a small glass globe exhausted of air, and the radiations from the flame of an ordinary candle placed at some sufficient distance away is sufficient to cause it to rotate with great liveliness.

A PAYMENT ANIMALCULE.—Prof. Leidy, of the Academy of Natural Sciences, describes in recently published proceedings of that body a curious animalcule which he discovered on street pavements. It is named *gromia* and resembles a cream-colored ball about 1-16th of a line in diameter. When placed in water, it in a few minutes projects, in all directions, a most wonderful and intricate net. Along the threads of this net (which are less than 1-30,000th of an inch in diameter) float minute *navicular* from the neighborhood, like boats in the current of a stream, until, reaching the central mass, they are swallowed. Prof. Leidy states that during dry weather the creature remains quiet in the dust, and that when rain falls it spreads its net and gathers food.

SOUND MADE VISIBLE.—A sound writer, called an opescope, is a new invention. On the end of a two inch tube is pasted a piece of thin rubber or tissue paper. In the center of this is fastened a piece of looking glass, one-eighth of an inch square. Hold this end in the sun and the other end in the mouth, and sing or speak in it. The ray of light reflected from the mirror falling on a white surface describes curves and patterns differing for every pitch and intensity, while the conditions give uniform results.

In a chemical lamp, with a clean wick, be filled with a mixture of alcohol and glycerine, in equal proportions, it will burn until the last drop has been consumed, and with as useful a flame as if alcohol alone had been used. The wick must be carefully cleansed when the lamp is laid aside; otherwise it will become clogged and unfit for use.—*Engineering and Mining Journal.*

NEW MODE OF HARDENING SANDSTONE.—In Saxony, sandstone is soaked in a solution of alkaline silicates and of alumina. The liquid penetrates some inches into the stone, and renders the surface so hard that it resembles marble and will bear polishing. On being heated to a high degree, the surface vitrifies, and it may be colored at pleasure.

Sales at S. F. Stock Exchange.

The Mining Share Market.

As will be seen by our stock tables and lists of sales, the market for mining stocks continues very dull. Holders manifest a disposition to realize on very slight advances, and just at present no "big rise" is anticipated. The dividends declared this month are numerous, as will be seen by reference to our "Shareholders' Directory." California is expected to begin paying dividends in May, and then pay \$3 per share. There have been no special features of note to speak of in the market of late, the prices having been apparently fixed at about the same figures, with slight fluctuations. Several more companies are about to divide up their capital stock. The Yellow Jacket company have called a meeting for March 15th to consider and take action upon the proposition to increase the amount of the capital stock \$9,600,000, that is to say, from \$2,400,000, divided into 24,000 shares of \$100 each, to \$12,000,000, divided into 120,000 shares of \$100 each. The Knickerbocker company hold a meeting March 20th, to take into consideration and decide upon the proposition to increase the capital stock of said company from two million four hundred thousand dollars (\$2,400,000) to five million dollars (\$5,000,000), divided into twenty-four thousand (24,000) shares, of the par value of one hundred dollars per share, the present capital stock of said company, to ten million dollars, (\$10,000,000) to be divided into one hundred thousand (100,000) shares of the par value of one hundred dollars (\$100) per share. REPORT OF THE MARVELOUS RICHNESS OF THE BUNNELL MINE, near Kernville, have been followed by the news that the mine has been jumped by parties who are holding possession of it by force of arms. An expensive lawsuit, if not bloodshed, is the next thing expected.

BROWER.—Owing to an over-supply of ore in the dumps, the mine was shut down for a couple of days during the week, but was started up in full blast again this morning. The mills on the river have been bothered somewhat with ice for the week past, so that the amount of ore crushed will not be as great this month as last. There is no change in the ore breasts or the quality of the ore extracted. The prospecting drift south on the 1500-ft level is steadily advancing, but shows no change of value to report. The water still is being removed from the reservoir of work on the 1000-ft level. The air shaft is being extended downward toward the 1500-ft level. The hoist pit for the new powerful pump at the air shaft is completed. The first tank station of the shaft is also completed.

THE GOOD FRIDAY is looming up, and promises to rank among the best mines of the State. The work of opening the mine goes on and with the most encouraging result. Twenty tons of ore from their mine have been crushed at the Pugh mill during the month just closed, yielding the large return of \$195 per ton. After paying all expenses the owners of the mine have a surplus of over \$1,000 left. That this is encouraging, none will deny.

PROSPECTING is progressing vigorously, and a number of promising ledges are being examined. The lucky strike made by George Hurst recently has stimulated others to try their fortune, and it would not be surprising if other rich mines are discovered.

NEW HYDRAULIC MINE.—*Herald*, Feb. 12: A new hydraulic mine, we learn, is soon to be opened on the North fork, about opposite Clipper Gap. The claim has been well prospected and with the most flattering results. Every new enterprise adds to our wealth. Let them increase. There is no illuit to the opportunities in this comparatively new, yet extremely productive county.

CUEVAO FURNACE has been running quite successfully during the past week on Bells Union (one of the Geco Con. mines) ores. There are now on hand about 100 hers, some 1,100 having been shipped. There is now at the furnace for reduction 300 tons of ore, but in consequence of snow in the mountains a sufficient supply of coal has not been obtainable and the furnace has shut down for a few days until coal can be had.

ST. GEORGE.—Saturday last we visited Lookout district and took a look at the St. George mine, of which we have heretofore made mention. It is an immense gold bearing quartz ledge, easily traced by croppings on the surface a distance of one mile, having its course southeast-northwest. Upon that portion of the course

ble ledge claimed by the St. George company, in several places, we chipped off the surface rock and found it pure. The rock is a fine-grained and containing much sulphurets. George Thompson, the managing genius of the St. George, and he is doing good work in the country, putting it in shape. He makes his horn spout a few every day and thinks he can tell within a very few dollars what every ton of rock is worth now on the dump. If surface showing is any indication he has a good idea of what any one can see from the surface that is extensive. Old time miners have been in the park of Mr. Thompson's hospital in the way of a good miner's cover, which we enjoyed to the fullest after our ramble over the hills and rocky canons.

LIONHOUSE.—This mine is also in Lookout district, just south and running parallel with the St. George, and the rock is similar to and shows the same mineral. The ledge is easily traced, having equal prominence on the surface with the St. George, and has several separate locations upon it. Mr. P. Reddy, we learned, is the fortunate owner of one claim, upon which work is progressing. The two ledges (the St. George and the Lionhouse)

the Lighthouse), similar in character and having a parallel course, in our judgment, are the main leads of that immediate range. They are in a granite formation—just such a section as an old gold quartz aarp would look for were he out prospecting—and not unlike some of the best gold producing localities in older portions of our State. We would state here that an abundance of water can be found in the immediate vicinity of these mines.

THE IDA MINE.—This prettily named mine is located on an independent mound near the mouth of Snow canon, and is on a line with the St. George ledge, further southeast and near the western side of Panamint valley. The croppings are similar to the St. George and Lighthouse, but so far as prospected do not appear to be as rich with free gold. For convenience we like the location of the Ida very much, and we have no doubt it will make a good show in mineral as work progresses and handsomely reward the locator, that he may return to or send for the loved one who was before his mind's eye when he said, "the Ida."

NEVADA.
WHAT THE FRYER PROCESS IS DOING. — *Foothill Tidings*, Feb. 12: Meadow Lake ores, hitherto so refractory and intractable as to defy all efforts to obtain even 10 per cent. of the precious metals contained, are made to yield up their wealth without stint by the Fryer process.

THE PROSPECT.—The Omaha and other mines down along Wolf creek have lately been sending ore to the Fryer works for test by the new process, and with the most gratifying results; that from the Omaha turning out nearly double the yield obtained by mill process. Prospect stockholders are feeling well over their mine.

THE OMAHA MINE.—The Omaha mine, situated in that once famous region of rich mines—and now becoming to again—between the Istocky Bar and Allisou Ranch, just below New York Hill and close by the Lone Jack and Homeward Bound, has lately been showing of what mettle, or metal, she is made. A run of 15 days through a 10 stamp mill, 175 tons crushed, finished on Saturday last, gave a yield of \$9,000 or nearly \$55 per ton. The ledge is said to be large and good.

PLACER.

THE MINES AROUND OPHIR.—*Argus*, Feb. 12: The mines in the Ophir district are looking better than ever. The St. Patrick company, after great perseverance and many disappointments, have at last struck their

showed. Last month we detailed their operations and enhanced the good fortune in store for them. The work for January more than confirms all the brilliant hopes which were entertained. The quantity of running water available is far richer than any yet extracted. The body of it exposed is sufficient to supply their present milling facilities for years. During the month of January the mill crushed 440 tons of ore, from which was extracted 303 ounces of bullion. The St. Patrick bullion was sold at 100.00 per ounce, and the balance of the month \$14,171.75, an average of over \$32 per ton. Owing to the heavy rains which have saturated the ground, it was impossible to get up steam enough to run the stamps, and the running time of the mill was reduced to 10 days. Had the 15 stamps all been run the full month the yield would have increased full one-third, as there were several hundred

MINING EXCITEMENT.—The people of the northwest-
ern part of the county have been considerably agi-
tated recently by the announcement that an analysis
of the ore from the Bear River iron mine, lately made by
Prof. J. C. Davidson, of the University of California, re-
veals the development of a fact that it contained nearly
three per cent. of the element, which is so exceedingly
valuable, and is so very rare, and accordingly
is of very precious mineral, known as tellurium, which is
variously estimated to be worth from \$3,000 to \$5,000
per p. nd. We know but little of this substance,
though it is said to be so hard that an instrument made
of it will cut through common steel as steel cuts
through hard wood. It is, like, combined with other
rare qualities, that gives it such a high value. If the
ore in this mine contains, besides its fair percentage of
iron, a small amount of tellurium, as it is credited
with, and the tellurium is worth, say five hundred
pound, we do not wonder at the people in the section
of the country where it is located becoming excited,
for it is certainly the biggest thing on the Pacific coast,
the great bonanza not excepted.

THE SEASON PROSPECT.—Weaverville Journal, Feb. 12: In a mining point of view the present winter is decidedly the best ever experienced in this section. The water supply commenced earlier than usual and has continued continuously, with a certainty of lasting longer than any previous season. The mountains are covered with snow many feet deep. The storms have come with such regularity and at such opportune times, that we don't believe the miners themselves could improve or the present season even had they the power to control the elements. Cold weather has not in the least interfered with the working of the mines, and, in fact, everything in the weather line has been just as good and beneficial as possible. The miners from one end of the county to the other are improving their time and the spreading opportunities presented by the favorable season. Many of them are working continuously, and there are none but have done much more work this winter than all of last year. As indicated by the few partial clean-ups thus far made, our mines should yield as much this season as they have during the past three or four combined.

TUOLUMNE.

GARATE Correspondence of the *Independent*, Feb. 12: The Nonpareil company at Deer Flat steadily prosecuted the work of driving a tunnel, which has, after many years of toil, and the expenditure of not less than \$60,000, reached the vein several hundred feet below the surface, and they are now amply rewarded for their toil and endurance by the discovery of large bod.

Expense—only three miners being required to keep a ten stamp mill supplied with rock. The mill is driven by a steam engine of 30 horse power, which through an eight inch pipe with one and a half inch nozzle, coming upon a ten foot hurdy gurdy wheel, which gives a powerful and steady motion. Water costs only \$4 per day. They have also a steam engine nearly ready which is intended to be used when water cannot be had. There is a fair percentage of rich sulphurates in the rock, and to save these a concentrator is attached to the mill, which concentrates the ore without much labor and very little loss. The Banders mill and mill is located on the North fork of the Merced river, and has been in operation with only an occasional suspension for many years. The mill is propelled by an over-shot wheel; water free most of the year. The rock is usually abundant and always rich. It also contains a very small percentage of very rich sulphurates. It is owned by one of Schofield's concentrators. The Superintendent, Mr. J. W. Brown, informs that the mill has recently struck it richer than ever in the lower levels, and are now running their ten stamp mill on excellent ore, with fair hopes that it will long continue. The company are now erecting a turbine wheel for the purpose of compressing air for a Burleigh drilling machine, as they are about starting a tunnel near the river, and to strike the vein low down and also have a detour.

Messrs. J. W. Tripp & Co., the principal owners of the above mine, also have recently purchased several mines on and near Big creek, and are now engaged erecting a ten stamp mill with most of the modern improvements now in use. The power is a turbine water wheel with 44 feet fall. The mines have formerly been worked, and ore crushed by a five-stamp mill, which had nearly rotted down, and has been entirely removed to make room for the new one, which leaves a very solid structure, and is expected to be ready to run in about three weeks.

On Diamond gulch, about one mile from this place, there is a two-stamp mill which runs by compressed air—the air being compressed by steam power. The stamps are said to weigh only 250 pounds, but strike with a force of 1,500 pounds, and crush from seven to ten tons per day. I cannot say at present whether this machine is a success or not.

ALTA.—Gold Hill News, Feb. 10: Sinking the main shaft is going steadily forward, the bottom in good working ground, and excellent progress is being made. Gwing to the strong pocket of water recently struck, the company has resolved to commence the erection of pumping machinery of the same pattern as the Consolidated Virginia.

AMAZON AND GLASGOW.—A day or two since a strong flow of water was encountered in the north drift on the 300-ft level, which has driven the men out, and stopped work in that portion of the mine at present. The ore vein is showing strong and heavy going northward, and some good results are confidently looked for when the water is once extracted. A large Blake's pump has been ordered and already shipped from San Francisco, and will arrive in a day or two more. As soon as it arrives it will be set up, and work in the mine resumed. New boilers have also been ordered and will arrive about the same time as the pumping machinery.

BALTIMORE AND AMERICAN FLAG.—Sinking the main incline is going rapidly forward, the bottom in good working ground. The pumps are finished and working finely, down to the 1050-ft level. The main east drift on the 1000-ft level is still advancing, the face of the drift in ledge material of a favorable character. The new air compressor for driving the Burleigh drills is placed at the bottom of the incline. The water pipes are now laid in position, for connecting with the drill at the bottom of the incline, much better progress may be expected in sinking the incline.

BEST AND BELCHER.--Still repairing the double winze below the 1600-ft level, having 38 feet yet to go to reach the 1700-ft level.

BULLION.—The northwest drift on the 2000-ft level of the limerick is steadily advancing toward the ore vein. The upraise from the 1700-ft level, to connect with the bottom of the incline, is also making excellent headway. Sinking the main incline below the 1400-ft level is being pushed forward at the rate of four feet per day. The erection of the ore shutes at the 800-ft

LEVEL is making good progress.

CALIFORNIA.—Sinking the main shaft is making steady headway. The pump at the 800-ft level is finished. The flow of water at the bottom of the shaft is not so great as it was a week or two since, and the pumps are now handling it with much greater ease.

CALIFORNIA.—The north drift on the 1550-ft level is still advancing, the face in good ore. Another winze has been started from cross-cut No. 5 to connect with the lateral north drift. The south drift on the 1550-ft level, Sinking the C. & C. shaft goes vigorously forward, the bottom in good working ground. A small engine has been erected to be used in lowering the heavy pumps and columns into place. This will be a great improvement over the old style of lowering them by hand, and assist greatly in the prosecution of the work.

CAOLLAR POSI.—Daily yield, 50 tons of ore, the assay value of which is \$28 per ton. No change in either the yield or quality of the ore extracted. The south drifts on the 1250 and 1350-ft levels are both steadily advancing, with no new or favorable indications to note. Sinking the Combination shaft is making excellent progress.

CONS. VIRGINIA.—Daily yield, 650 tone of ore, keeping the mills all running up to their full crushing capacity. There is no apparent change in the appearance of the ore breasts or the quality of the ore extracted. The shipments of bullion up to last evening were \$258 - 445.56, in excess of that of January at the same date in the month, a showing that proves conclusively that the returns of the new California mill is beginning to make itself known. The California mill is now crushing regularly 300 tons of ore per day. The pen mill has a capacity of about 350 tons. The cold, snow weather of the past few days has not interfered in the least with the operations of either mine or mills, and the prospects are, that although a short month, the yield of bullion for the month of February will exceed that of any previous month since the opening of the great ore body.

CAWON POINT.—The usual amount of ore is being extracted and milled, without any change in quality or value. The main east drift from the 1700-ft level is steadily advancing, without having yet reached the south winze. The main west drift is about 100 feet from the south winze. The drift is in fine quartz and low grade ore, which gives average assay of \$12 to \$15 per ton. The main south drift on the 1600-ft level is still showing some excellent ore prospects, and has about 70 feet to yet run to connect with south winze No. 2, which is being sunk from the 1600-ft level. This winze has about 70 feet to sink to reach the level of the 1600-ft drift. Soon as the connection between the two levels is completed, and ventilation obtained so as to permit it, cross-cutting will be started to determine the width and extent of the ore body on the 1600-ft level.

DAYTON.—Sinking the main shaft is making excellent progress, notwithstanding the rock in the face is somewhat harder than it has been for some time past. The north and south prospecting drifts, on the 500-ft level, are steadily advancing, running parallel with the ore vein. There are no new features to report of these drifts. The main couth drift, on the 300-ft level, is also making good progress. No change in the character of the rock.

FLORIDA.—The new hoisting machinery being placed into position is of a powerful and substantial description, and will do effective service.

GOULN & QUARRY.—Re-timbering the main shaft is going steadily forward. Nothing doing yet on the 1700-ft level.

HALE & NOACAOS.—The mine is still flooded by the flow of water from the Savage. The pumps are kept running up to their full working capacity, but as yet produce no impression on the immense body of water with which they have to contend.

IMPERIAL EMPIRE.—Daily yield, 40 tons of ore. The ore breasts show but little if any change during the week. The main north drift on the 2000-ft level is showing very favorably, and is steadily advancing toward the north line. Nothing new to report of any of the other prospecting drifts.

JULIA.—Sinking the main shaft is going forward at the rate of five feet per day, the Burleigh drill operating splendidly, and the work being pressed with all energy possible. The main southwest drift on the 1600-ft level is also being penehed vigorously forward, the face in very favorable vein matter. The main northeast drift is being penehed at the rate of steadily advancing at the rate of four feet per day. No material change in any other portions of the mine.

JURTOR.—Face of the south drift at the 800-ft level in low grade ore. A winze is being sunk from the 600-ft level to connect with the 800 for air circulation purposes and exploration. It is being sunk at an eligible point and will be completed to the 800 in three or four weeks; it is to be eventually completed to the 1000-ft level. A plunger pump is put in to reduce the water and aid operations at the 1600-ft level, mining next to the surface and the 400- and 600-ft levels is suspended on account of the bad state of the roads, preventing hauling onto the mill.

KNICKERBOCKE.—The pumps are kept steadily running and are doing excellent work, steadily lowering the water in the shaft. There is now but a few feet of water in the sump, and that will be exhausted in less than a week's time. When this is accomplished the long delayed work of developing the lower levels will be vigorously pushed ahead and the Knickerbocker will come to the front.

KOERTZ.—Sinking the shaft is progressing at the rate of five feet per day. The main south drift on the 500-ft level is advancing steadily, the face in fair working ground. It is now in 130 feet. The main south drift on the 350-ft level is now in a distance of 420 feet, the face in fine quartz and low grade ore. The east cross-cut from this drift has penetrated the ore vein a distance of 70 feet, the face being still in fine quartz.

LADY BETAN.—Sinking the main shaft is going steadily forward, the bottom all in quartz and ore. The cross-cut from the south level is also making good headway, and is coming to a level very nearly parallel with the course of the drift. \$50.00 of this ore are very rich, assaying as high as \$100.00 per ton. Average assays give a result of \$40.00 and upward for the present. The drift is about 250 ft. thick, and is also showing a steady improvement, and will in all probability soon strike the same rich ore found on the level above. Cross-cuts on the 330-ft level are being made in the direction of both the north and south headings.

LADY WASHINGTON.—The pump column is completed, the plunger and rods in place to-day, the tank and station at the 530-ft level finished, and to-morrow the

California and Colorado Loco Poisons.

The following paper was read before the California Academy of Sciences by Dr. A. Kellogg.

During the last generation, or about fifteen years ago, the poisoning of horses, cattle and sheep, by the cattle-weed, Pompona pea, or Pop pon, Menzie's milk vetch, (*Astragalus Menziesii*—Gray.) of the vicinity of San Francisco, came to our knowledge, and innumerable instances since, reported from all parts of the coast where it abounds, have only served to confirm these observations. How long it has been known to the native Californian, we are unable to say; but reiterated experience has taught sad lessons to independent observers everywhere. To some, however, the cause of their misfortunes is still a mystery. We have reason to know that there are also other similar causes of which we shall treat hereafter. This subject has been frequently brought before the Academy, but no record hitherto appears in the proceedings. This and some allied forms have been figured and published here, so that the public may have supposed to be somewhat familiar with it. The plant has much the appearance of bladder fern. As no chemical analysis has been made, nor any carefully noted experiments tried on animals, all we know is the serious results, often obscurely and imperfectly reported by the farmer, ranchero, herder and the shepherd.

Horses and cattle in this vicinity, we notice, shun it so long as the pasturage is good, but as it becomes bare and hunger impels, they bite it and become narcotized, or as we may say, intoxicated; they stagger and are unsteady in all their movements, act strangely and stupidly, and seem to lose their good horse sense or common brute sagacity, acting like a fool; hence the Mexican name "loco" given to it. At length they become thinner and cannot be restored to "condition"—they get to like the weed more and more, apparently infatuated, as the Sandwich Islander for his ava (*Crucian Piper methysticum* in water), or the drunkard for his bottle; if only slightly "locoed" they are scarcely fit for general use, because so unreliable in perilous paths, or emergencies, acting so like fools, to the shame of all sensible animals. What is most remarkable with both this and the Colorado "loco" is the permanence of the impression, often lingering for many months or even years, half demented, until at length they die.

Death often supervenes suddenly; the effect is similar with horned cattle and sheep. This rattling weed is by no means confined to damp ground, but thrives equally on dry hills, in all soils. It has a tall and leafy stem or stems in bunches from a common perennial root, leaflets many paired (twenty or more), stipules at the base of the leaves triangularly membranous—flowers, dirty pale yellowish or whitish tinged with red, mostly but forcibly back. Pods inflated, about two inches long and thinly membranous, indeed so bladder-like that boys amuse themselves by popping them—hence the name "Pop pea."

Herders are in the habit of "prospecting" their proposed pastures, especially for sheep, before moving their flock. A few, rather than shun or abandon their fields, have very sensibly made war on it with the grubbing hoe; others less cautious, or totally ignorant, have lost as high as \$800 in one instance. I have been told that miners eat the beans with impunity, and some have contended that the poisoning is from worms on the weed—fungi also have been credited with it. Had we not an allied Colorado "loco" and the *Tephrosia*, or devil's shoestring of the South, which stupefy and intoxicate, besides others corroborating, some doubt might possibly be entertained.

Lamher's milk vetch of Colorado, *Oxytropis Lamheri*, Pursh, (*Astragalus Lamheri*, Spreng), consists of about six to eight varieties, for which, for all popular purposes, one description might suffice. Roots perennial; they are all stemless, or nearly so—not considering the flower or fruit scape as such; they grow in tufts or stool-like suckers, spring out by very short branches from the root crown; are more or less silvery, satiny, silky in every part; the common leaf stem is about three inches long, the upper oddly pinnate portion nearly equal, or the whole length of leaf about six inches, but much shorter than the flower scape stem; the pea blossom flowers purplish, or blue and white, violet or ochroleucous; leaflets, three to fourteen pairs, usually about eight or nine; stipular appendages at the base of the leaves, at or under the soil. Sheathing pods white, satiny, silky, with short, close pressed hairs, erect, somewhat cylindric, one-half to one inch long, sharpening out at the point and partly two-celled.

Found from Saskatchewan to Texas, New Mexico, West to Rocky mountains, and Colorado to Washington Territory, and according to Hooker, to Arctic America and Labrador.

Of this species of loco we have no personal observation. Assistant Surgeon P. Moffatt, U. S. A., writing from Fort Garland, Col., says cattle men inform him that the weed abounds in damp grounds among grass, and poisons many horned cattle and horses; he is assured that after eating it the animal may linger for many months or a year or two, but they invariably die from its effects. The animal does not lose flesh, apparently, but totters on its limbs and becomes crazy. While in this con-

dition a cow will lose her calf and never find it again, and will not recognize it when presented to her. The eyesight becomes affected, so that the animal has no knowledge of distances, but will make an effort to step or jump over a stream or obstacle while at a distance off, but will plunge into it or walk up against it on arriving at it. The plant pointed out to him seemed to be related to the lupin.

Our Exports by Rail.

From its situation, this city ought to have a large and growing trade with all interior parts of the continent accessible by rail from this city. The expectation that the transcontinental road would be the medium of an active commerce between the East and the West, it was which induced the nation to aid the project so lavishly with credit and lands. To a great extent, this expectation has been realized, but not to as great a one as the people of the Pacific slope have had reason to expect. We do not now care to enter into the causes of this; suffice it to say, however, that the future points to the growth of a vast and important trade between this city and the commercial centers of the Mississippi Valley, the Atlantic slope and Canada, nay, even far distant Europe. In our progress towards this consummation, however, we must expect an occasional set-back, and such a one we have received during the past year, to judge from the annual statistics recently published by the railroad. They show that there has been a decline in the amount of freight carried East by rail of 35,041,942 pounds as compared with 1874; that is a decline of about 25 per cent. This decline has taken place principally in Barley, and in General Merchandise (unspecified).

Of Antimony, a new export by rail, 265,074 pounds were shipped during the year. Of Barley, only 58,282.31 cents were shipped as against 378,964.23 cents in 1874. This shows a great falling in of Eastern demand. Of Borax, we sent 1,320,157 pounds, somewhat less than the shipments of 1874, though double those of 1873. Of Beans, 436,833 pounds were shipped as against 101,930 pound in 1874, and a smaller quantity in 1873, showing an increase of over 450 per cent. We shipped 23,000 gallons of Brandy East and 400,000 gallons of Wine, as against none of the former and 500,000 gallons of the latter in 1874. About one-third more Coffee was shipped to St. Louis and Chicago, to relieve the market, than in 1873, the figures being 926,353 pounds for the former year and 1,281,384 pounds for the latter. A heavy decrease is notable in Green and Dried Fruits, of the latter only one-seventh, and of the former, only a third of the amounts of 1874 having been shipped. The quantity of Hops shipped in 1875 was only 326,172 pounds as opposed to 794,186 pounds in 1873. In Leather a decline is also noticeable, the amount for 1875 being only 558,222 pounds as opposed to 735,739 pounds in 1874. The amount of General Merchandise shipped in 1875 was only 4,278,542 pounds, whereas it was 8,230,123 pounds, or nearly double, in 1874. There was an increase however in Salmon, the quantity going East in 1875 being 112,000 cases as against 107,000 cases the previous year. Of Quicksilver, 798,232 pounds were shipped in 1875 and 425,435 pounds in 1874. The quantity of Silk in 1875, sent overland, was three times that of 1874, while that of Skins and Furs was nearly sevenfold. Of Syrup we shipped 220,000 gallons in 1875, not half of that shipped the previous year. The quantity of Tea increased in 1875 by seven million pounds over 1874. And the increasing product of Wool is shown in shipments of 39,315,966 pounds last year as opposed to 30,169,191 pounds in the previous year, and 26,100,964 pounds in 1873. All these figures apply to shipments from San Francisco. The following tables, taken from the columns of a commercial contemporary, give the exports by rail in detail:

	1873.	1874.	1875.
Antimony.....	265,074	265,074	265,074
Alfalfa Seed.....	3,453	5,522	5,522
Almonds.....	100	100	100
Barley.....	1,217,081	37,896,423	5,828,241
Borax.....	619,449	1,497,360	1,320,157
Beans.....	98,349	101,930	436,833
Base Bullion.....	40,436	40,436	40,436
Butter.....	230,889	250,513	2,590
Brandy.....	181,851	181,851	181,851
Bacon.....	12,840	12,840	12,840
Building Materials.....	12,840	12,840	12,840
Copper.....	410,855	410,855	410,855
Cocoons.....	20,742	20,742	20,742

USEFUL INFORMATION.

Pedestrian Training.

Pedestrianism, as an athletic exercise, has become deservedly popular. There is no course of gymnastics so well calculated to develop a large number of muscles, or to produce so beneficial an effect upon the system. There is a right way and a wrong way of walking—the one beneficial, the other negative in its result. What the right way is, a writer in an English contemporary tells us in the following:

The body must be held erect, with head well thrown back; the movement of the legs must be from the hip downward, and the body should be carried motionless. The arms should be swung well forward in harmony with the legs, and the elbow should, when in front, be nearly on a level and at almost right angles with the chin, the hands being open and extended. The leg should be brought well round from the hip, and the heel deposited on the ground in line with the rear foot, so as to leave your foot-marks pretty nearly in a line. But above all things hold your head up and the body erect.

Stitches and other kindred annoyances are common in learning to walk, but the beginner would do well to walk it off, and never ease if seized with distress. To do so is to throw away the pace he has acquired from the commencement of his walk, and to knock all the regularity out of his stride.

FACTS WORTH REMEMBERING.—A correspondent gives the following useful recipes: If you have been pickling or handling any acid fruit, and have stained your hands, wash them in clear water, wipe them lightly, and while they are yet moist, strike a match and shut your hands around it so as to catch the smoke, and the stains will disappear. If you have stained your muslin or gingham dress, or your white pants with berries, before wetting with anything else, pour boiling water through the stains, and they will disappear. Before fruit juice dries it can be often removed with cold water, using a sponge and towel if necessary. Rubbing the fingers with the inside of the paring of apples will remove most of the stain caused by paring.

To clean and restore the elasticity of cane chair bottoms: Turn the chair bottom upward, and with hot water and a sponge wash the cane; work well, so that it be well soaked; should it be dirty, use soap; let it dry well in the air, and it will be as tight and firm as new, provided none of the canes are broken.

Match mats can be made of ordinary sand paper, cut in circular and octagonal shapes, fastened upon pasteboard and bound with bright-colored braids, a riag attached to each, and the whole hung near the match safe for use whenever a match is lighted. The unsightly marks that disfigure many walls may, by this inexpensive and simple arrangement, be entirely prevented. There should be one in every room in the house.

A Pre-Historic tomb has recently been discovered in Dedham, Mass., at a point near the banks of the Charles river, about nine miles south of Boston. The tomb consists of a horizontal 10-foot excavation into a hill—the mouth of the arch of Roman shape, the walls and floor carefully built of unhewn stone, laid in mud plaster, innocent of lime. The central portion of the tomb was about 10 feet in diameter each way. A mass of masonry, unconfined, and apparently the remains of an incriminated body, occupied the center of the floor. No other remains or relics of any character whatever were found.

Various speculations are indulged with regard to the origin of the subterranean structure. It certainly was not of Indian origin, and differs altogether from any of the pre-historic remains so plentiful in the Mississippi Valley. Was it the remains of one of the early Norsemen who are known to have visited that coast some centuries before the discovery of Columbus? Most likely it was. It is not far from the famous Dighton rock, so well known from its curious, and, as yet, uninterpreted inscriptions; or from the spot where the body of a helmeted warrior—an undoubted European—was exhumed a few years ago. The Cambridge savans have the matter before them for elucidation. Their report is awaited with considerable interest.

AIR AND SUNLIGHT.—From an acorn weighing a few grains, a tree will grow 100 years or more, weighing several tons. A large part of this growth is derived from the sun, air, and water—but little from the earth. Wood and coal are but condensed sunshine, which contains three elements equally important to animal and vegetable life—magnesia, lime, and iron in the blood, which gives it its sparkling red color and strength; the lime in the bones imparts to them the durability necessary to bodily vigor, while the magnesia is important to many of the tissues. Thus, the mere sunlight we enjoy the healthier we shall be and the longer will life endure.

To remove tarnish from plated goods that have turned dark from the action of gas, steep the plated ware in soap lye for two hours, then cover it over with whiting, wet with vinegar, so that it may stick well upon it, and dry it by the fire; by thus drying the whiting is removed from the crevices without the least difficulty. Rub off the whiting and pass over it with dry bran. The silver will look exceedingly bright.

HOW THE INNER SURFACE OF GLASS REFLECTS LIGHT.—Some one asks the *Scientific American* to explain the reflection of a ray of light from the inner surfaces of glass, diamonds, drops of water, and other transparent substances, causing the brilliancy of the diamond, the formation of the rainbow, etc. That journal answers as follows: The reflection from the inner surface of a transparent medium is similar to that from the outer surface. (Observation and experiment have proved that it is a universal law that, when light passes from a dense into a rare medium, or vice versa, a part of the light is reflected in such a direction that the angles of reflection and incidence are equal. When, therefore, the surface between the two media is perfectly even, it acts like a mirror, and the smooth surface of still water is as good a reflecting mirror for the fishes under it as for men above, of which fact you may easily satisfy yourself by observing an aquarium. A piece of plate glass will also convince you of this by two reflections, one from the front and one from the back or interior surface, giving you two reflected images, which will coincide when the light falls perpendicularly, but become separated when the light is made to fall obliquely. The colors shown by diamonds or raindrops in the rainbow are not due to this reflection, but to the refraction of the rays when they enter and leave the diamonds or water drops; for the explanation of this we refer you to any modern text book on natural philosophy.)

BOILING OIL.—The *Industrial Monthly* says: Do not buy oil which has been treated with litharge, burnt umber, red oxide of lead or vitrol (blue or white,) or sugar of lead, or manganese, or any other siccative. Oil should be boiled in a copper kettle, if possible, set in masonry, and should be thoroughly stirred. While boiling, pieces of toasted bread should be occasionally floated on top of the boiling oil to remove the moisture; pieces of charcoal would answer the same purpose, and would do for fuel afterward. A furnace should be situated in the open air so as to allow the disagreeable vapor to escape, and should be built in such a way that no smoke or blaze could get to the oil, for if your oil gets smoked, it will spoil it in a measure for light colored work, and if the blaze can come near the oil, you run the risk of a fire, as oil at a high temperature evolves an inflammable gas. With oil prepared in this way you can do a better and more lasting job, and will find it to wipe out easier and not show so many brush marks; will not crawl if your under coatings are dry. Your wearing varnish will not strike in any more in one part than another.

PURIFYING WATER WITH ALUM.—Alum will only purify water from organic impurities, which it will precipitate in the same manner as it precipitates dissolved coloring matter in the manufacture of lakes from dye woods, etc. One teaspoonful of pulverized alum in four gallons of water is sufficient; if the water contains such an amount of impurities that this quantity will not purify it, it is unfit for drinking purposes. In the artificial manufacture of ice from Mississippi river water, at New Orleans, this method is employed to purify the water before freezing it.

HOW WHITE SHIRT BUTTONS ARE MADE.—Some varieties of these buttons are made as follows: Finely powdered statite is saturated with soluble glass, dried and repulverized, and the powder thus obtained is pressed into molds by suitable machinery. They are then baked or fired in ovens, again dipped in solution of soluble glass and subjected a second time to the firing process. When cold they are polished by being placed in a rotating cask with water, dried, and again polished by rotation in a similar cask with soapstone powder.

AN ANCIENT WOOLLEN FACTORY.—At Pompeii a small woollen factory has just been discovered, near the house where the renowned fresco of Opheneas was recently found. In this factory are still seen pieces of woollen cloth, quite carbonized, and many instruments for carding and weaving similar to those used in some small factories of this kind at the present day.

A FAST YACHT.—Buffalo has a new steel built steam yacht, only 80 feet long, 10 feet beam, which runs at the rate of 20 miles an hour.

PERPETUAL INK FOR TOMBSTONES, ETC.—Pitch, eleven pounds; lampblack, one pound; turpentine sufficient; mix with heat.

GOOD HEALTH.

PARALYSIS.—One of the physiological observers of men and things says paralysis is becoming a common disease. It is not confined to the fleshy, the plethoric, nor the aged. The fast life of our young business men tells on them. It is a very common thing to see men of 30 and 35 bald-headed, feeble gaited, and walking about with canes, their underpinning knocked out, with other signs of premature age. These signs of early weakness develop in paralysis.

To prevent the skin discoloring after a bruise, take a little dry starch or arrowroot, merely moisten it with cold water, and place it on the injured part. This is best done immediately, so as to prevent the action of the air upon the skin. Invaluable for black eyes.

Childhood's Infectious Diseases.

The *Lancet* calls attention to the importance, in the present state of the public health, of securing the early detection of cases of scarlet fever. It is of consequence not only to the patient but also to the community, in order that timely measures may be taken for preventing the spread of the disease. The *Lancet* says that the throat symptoms are the most trustworthy for the purpose of diagnosis in the initial stage of scarlet fever. The soft part of the palate is extensively reddened, and not merely the tonsils, as is the case in the first instance in ordinary sore throat. When this condition is met with, accompanied by a very hot skin and a very quick pulse, accompanied or preceded by sickness, with a thickly furrowed tongue, red borders, and prominent papillae, a case of scarlet fever may be prepared for. In most cases, adds the *Lancet*, sickness occurs within 24 hours after the commencement of the attack, and in a large proportion of the cases it occurs within 21 or 18 hours.

The *Lancet* addresses itself to the medical men, but there are so many parents who have a wholesome fear of calling in the doctor to their families if they can avoid it, that it is well for the signs to be widely known during the present prevalence of scarlet fever, by which they may ascertain that they will have finally to resort to him. Seeing, too, the number of the children of the poorer classes now daily gathered together in schools, it would be a wise precaution for the authorities to issue to schoolmasters and schoolmistresses some plain directions for the detection of this and other infectious maladies common to childhood, by which, in the event of complaints of illness on the part of any of their pupils, they might become aware of suspicious cases and take their measures accordingly. In the absence of such or a similar safeguard, schools in crowded districts may play no small part in assisting the progress of the epidemics of the future.

SURGICAL TREATMENT FOR CONSUMPTION.—Professor Mosler, of Germany, is now successfully treating pulmonary consumption, by making an incision through the wall of the chest and drawing off the pus with the syringe, and afterwards washing out the ulcers with weak carbolic acid. No difficulty appears to have been experienced in the operation, and the condition of the patient was improved, the cough becoming less troublesome, and the febrile symptoms apparently moderated. One point, at least, is regarded as settled—and it is certainly one of great importance—so far as could be by a few experiments of this character, namely, that the local treatment of pulmonary cavities is undoubtedly practicable, and that the lung is really more tolerant of external interference than has been generally believed. The uses of carbolic acid are rapidly extending, and it bids fair to become one of the most valuable articles of the materia medica. It appears to be speedy death to diseased germs and fungus growth.

FUNGI IN DISEASE.—At a recent meeting of the Newark, N. J., Scientific Association, the President, Dr. Edwards, called the attention of the members to the connection of microscopic fungi with disease in animals and plants. In the discussion on the connection of fungi with diphtheria it was asserted that the parasitic fungus is always present in the diphtheritic membrane. Whether this was a cause or a simple accompaniment of the disease was undecided. Dr. Edwards stated that whatever would destroy the fungus would cure the disease, and that he had secured very satisfactory results by the use of salicylic acid.

THE HUMAN BITE.—Near Cincinnati, a short time ago, two men engaged in a fight. During the melee one of them bit the other's eyebrow off. The wound was not considered dangerous, but the next day the injured man complained of "sickness all over" and a dull pain in his head. He grew steadily worse until about a week after the trouble, when he fell dead while drinking a glass of water. Soon after death his body turned yellow, with black spots—symptoms, according to the medical practitioners of the place, resulting from the poisonous condition of the biter's teeth.

HOW TO SECURE OLD AGE.—An old Quaker, William Klinkerbeard, died about 1753, at Plymouth, N. J., aged 108. At the age of 107 he hoed in the garden with a young man on a very warm day. On finishing the work the young man threw off his coat and the old man instead put on a buckskin jacket, saying: "Ah, my boy, that is the way you shorten life, throwing off your coat when you are warm, while I put on mine." He was healthy in body and mind, and rode out when past 107 years of age.

ANOTHER REMEDY FOR NEURALGIA.—A Frenchman has discovered that a stream of water directed from a force pump against a spot visited by neuralgia will relieve it. The operation is painful, but patients "call for a repetition on a return of the disease."

GREEN LAMP SHADES.—At Bonn, Germany, headaches, dyspepsia, etc., affecting several patients, have been traced to evening studies pursued under the baleful influence of a green lamp shade, from which arsenic was set free by the heat of the flame.

DOMESTIC ECONOMY.

The Omelet.

How to Make a Good One.

We think our readers will sincerely thank us for the precise mode of preparing this delicious luxury, for the mind that invented the omelet was capable of greater things. Many persons think they have made and eaten omelets when they have not. Anything that is made of eggs stirred up and solidified over the fire is supposed to be an omelet, but it is not. I have heard of people who put flour in it. Flour takes 15 or 20 minutes to cook, and an omelet is made in one minute; and raw flour is not wholesome or appetizing.

The true omelet is a pile of terror-stricken eggs and milk; it trembles with every jar, and crouches in a delicious quivering mass upon the plate; he who puts a silver knife into it will find a porous, flaky material, almost impalpable to the touch, that will melt as quickly as a snowflake in his month. Upon reflection, he will be willing to admit that hens were not made in vain.

Proceed in this way if you wish to make an omelet: Have some fresh eggs, not omelet eggs. All eggs that will not by any possibility do to boil, are put away in restaurants to make omelet with. Break them into a china bowl. If they are fresh, the white will be as clear as a maiden's eye, and the yolk as round as the pupil of it. Add a tablespoonful of milk for every egg, and whip the whole as thoroughly as you would for sponge cakes. The omelet pan has previously been put on the fire and made so hot that butter will melt and almost brown in it, but not quite. When in this condition you are to turn the whipped egg and milk into the pan and put it directly over the fire. Get a thin-bladed knife and run it carefully under the bottom of the egg, so as to let that which is not cooked get below. If the fire is right the whole mass will swell and puff and cook in a minute; if it is not carefully attended to it will burn on the bottom, and burned egg is most offensive in smell and taste. It is not necessary to wait until the whole mass is solid, as its own heat will cook it after it has left the pan; but begin at one side and carefully roll the edge over and over until it is all rolled up, and then let it stand for a moment to brown, and turn it out on a hot plate and serve it, or, what is better, eat it yourself—immediately.

You must not pat one grain of salt in it while cooking, or all your hopes and your omelet will flatten down together. If it is properly made it will be like a summer sunset, rich with crimson and yellow hues, and the savor will gladden the heart.

The common mistake in making omelets is to merely stir the eggs with a fork; to put no milk in it; to put salt, flour and bread crumbs in; to cook them too slow, and to turn them out on cold plates, a clammy, skinny waste of eggs. Thus made, they are as unwholesome to eat as they are repulsive in appearance.

If any one has a fancy for mixing finely minced ham with the egg batter, they will have a ham omelet; or for surrounding it with stewed kidneys and smearing a little of the sauce thereof about the egg after it is cooked, they will have a kidney omelet, or by pouring run over it and setting the same on fire, they will have an "omelet au rhum"; or by sprinkling granulated sugar over it it will be an "omelet sucre"; but all these are simply inventions of the enemy to see how vilely they can ill-treat a good thing, and yet not utterly ruin it.

YELLOW PORK.—Pork sometimes presents a yellow appearance when it comes from the slaughterer's. Such appearance is due to a derangement of the liver—to a deposit of vitiated bile. It is analogous to what often occurs in the human family, and is one of those cases where slaughtering saves the life of the animal, as it would soon have died of the jaundice if it had been left alone. To use such meat as food may possibly do nobody any hurt, but it is better suited to be used for soap grease.

The cause of streaked butter is the imperfect working of the butter after it is salted. Salt in butter sets the color, or deepens and brightens it; so that if the salt is worked into the butter and not so fully worked as to salt every part, then the fresh butter retains the color it had when it came from the churn, and the salt butter grows so much darker that it is decidedly streaked. The remedy is to work the streaked butter more thoroughly.

BANLEY BROTH.—Take a breakfast-cupful of pearl barley, boil it in a gallon of water gently for thirty minutes, then take three pounds of meat—lamb or mutton chops, with the fat cut off, or lean beef—put them into a separate stew-pan, dress them with a small quantity of water, add to them any kind of vegetables—carrots and turnips, with small onions, celery, and green peas, if in season—salt, pepper, and, with the water and the barley let the whole boil gently for two hours or longer, and serve it up all together.

PEA SOUP.—After well washing one quart of split peas soak them for the night, and boil them with a little carbonate of soda in just sufficient water to allow to break to a mash. Then put them to three or four quarts of beef broth and stew for one hour; then pass the whole through a sieve and heat again. Season with salt and pepper.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions payable in advance—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Feb 19, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Father of His Country; An English Journal on the Hayden Survey; Vertical Wood-Boring Machine, 113. Incorporated Mining Companies; Latest from the Emma Mine; Facts from the Patent Office; The Rainfall; The Dip of the Comstock; Death of Dr. Logan, 120. The Yellowstone Falls, 121. Patents and Inventions; Notices of Recent Patents, 124.

ILLUSTRATIONS.—Vertical Wood-Boring Machine, 113. Lower Fall of the Yellowstone River, 121.

CORRESPONDENCE.—More about Straw Burning Engines, 114. Hydraulic Gold Mining in California, 121. Troubles of an Inventor, 125.

MECHANICAL PROGRESS.—Combined Iron and Steel—New and Important Inventions; Artificial Pig-Iron; Solid Castings; A Novelty in Steel Manufacture, 115.

SCIENTIFIC PROGRESS.—Measuring Earthquakes on Mt. Vesuvius; How Electricity Splits Trees; Sound Waves and Safety Lamps; Chemical Action of Water on Iron; Motive Power From Artificial Light, 115.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 116.

MINING SUMMARY from various countries in California and Nevada, 117-23.

USEFUL INFORMATION.—Boiled Oil; An Ancient Woolen Factory; Pedestrian Training; Facts Worth Remembering; How the Inner Surface of Glass Reflects Light; Purifying Water with Alum; How White Shirt Buttons are Made; Air and Sunlight, 119.

GOOD HEALTH.—Childhood's Infectious Diseases; Surgical Treatment for Consumption; Fungi in Disease; Another Remedy for Neuralgia; Green Lamp Shades, 119.

DOMESTIC ECONOMY.—The Omelet; Yellow Pork; Barley Broth; Pea Soup, 119.

GENERAL NEWS.—General News Items and other items on 123 and other pages.

MISCELLANEOUS.—Placer Mines in Kern County; Motive Power for the Centennial; Consolidated Virginia Dividends; From the Julian District New Mining District, 114. California and Colorado Loco Poles; Our Exports by Rail; Early Rising a Delusion, 118. English Built Steamers for the Pacific Mail S. S. Co.; The South Charist Mine, 122. Big Guns and Their Cost; Iron Rust a Cause of Fires; Electric Whistle, 126. New Incorporations, 125.

MORE INFORMATION.

During the coming season we intend to send out correspondents who will not fail to report promptly to us information of the most important improvements in the different districts they visit. This will make extra expense to us, and we trust to a liberal patronage of our improved reading columns to recompense us for the outlay. We expect the mining and mechanical industries of this coast to make great advancement this year, and we mean to improve fully the field of usefulness thereby open to the Press. We invite all interested in the progress of these industries to give the paper their support and send in their subscriptions and renewals without waiting to be called upon. Send at once by registered letter, or coin package by express, at our expense for transportation. We specially need the power of hard coin rightly due us, just now, to speed the Press onward!

The January product of the Belcher mine was \$325,500. A handsome surplus was carried over from the last dividend.

Incorporated Mining Companies.

Few people have any idea how many mining companies there are incorporated on this coast every year. We give each week in the Press a list of these incorporations, with the location of the property, capital stock, names of directors, etc. These companies are incorporated with a capital stock of from \$1,000,000 to \$10,000,000, the latter being the favorite figure now-a-days. To the uninitiated it would appear as if we had unlimited capital to invest in mines when so many companies are organized with such enormous capital to back them.

Unfortunately, however, this capital is only on paper, and a company with ten millions capital stock may be so hard up as to be unable to pay for the printing of the certificates which constitute its only available assets.

During the year 1875 there were 203 companies which filed certificates of incorporation in this city. The mines were mainly in Nevada, but some were in California, Idaho, Utah and Arizona. The par value of the shares is generally placed at from \$10 to \$100; but if the \$100 shares can be sold for \$5, or the \$10 shares for 25 cents, the promoters consider themselves in luck. Certain persons of some prominence in the community receive a certain number of shares free for the use of their names in incorporating, and further than this they seldom know anything of the property. Of course one or two interested parties or original owners are on the Board of Trustees. The manner of incorporating is simple, and is as follows:

The parties interested in a piece of mining property being desirous of forming a joint stock company, meet and adopt a name for the company. They then prepare in due form a certificate of incorporation, which sets forth the location of the claim, the intention of the company, names of trustees, amount of capital stock and its par value; this being signed and acknowledged is filed with the Clerk of the County Court in the county in which the principal place of business of the company is located. A certified copy is sent to the Secretary of State, and the parties owning in the mine then convey to the company all their interest in the mine and receive a certain proportion of stock for the same. The proper officers are then elected, the books opened and the stock issued. The institution is thus fairly afloat, either to become a permanent paying fixture, or to subside and die suddenly out. Its existence depends, however, more on the exertions of the promoters in disposing of the stock at "hedrock" prices than in the value of the property itself.

Although liable to abuse, the best method of working and managing the financial affairs of a company is by incorporation, as it facilitates business, enables parties interested to buy and sell or borrow upon their interest in the mine, and in various other ways brings undoubted benefits with it. For the facilitating of business, the collection of assessments and the general system of conducting the affairs of a company there is nothing like an incorporation. But the great trouble appears to be that many have conceived the erroneous idea that the simple form of issuing stock must necessarily give value to the mine it represents, losing sight of the fact that stock of any kind which does not pay dividends is substantially valueless. This public who buy the stock are gullible enough, however, to buy stock at what is known as "hedrock prices" without inquiring or knowing much of the property itself, trusting entirely to an advance in the price of stock for a profit. There are, however, hundreds of companies incorporated which are never heard of after the names appear as "New Incorporations." The system is the only one yet devised by which money can be raised for working small properties and in which each interested party is liable to loss or profit in proportion to the amount of stock he owns.

Latest from the Emma Mine.

There has been newspaper mention lately of a strike in the Emma mine. A private letter to a gentleman in this city, from a correspondent at Alta, Utah, furnishes the following information in respect to it and the character of the ore: A body of ore has been found in the Bay City tunnel which runs under the extreme westerly edge of the Emma mine workings, and is at least 400 feet west of the lower works. The tunnel level is 20 to 30 feet below said lower works. Ore found in the tunnel is poor; it assays from 3 64-100ths ounces to 15 79-100ths ounces per ton, with one to two per cent. lead. The superintendent calls that the average.

The ore body is continuous easterly and westerly as far as explored, say 20 feet each way, but it does not rise; in fact, it was found in the floor of the tunnel only, the roof being solid country rock. Vein matter seven to nine feet thick, with the mineral in seams and bunches.

The main shaft of the Rising Star mine, at Colfax, is now 580 feet deep and workmen are engaged on a contract to sink it to the 600 foot level. It is now the deepest mine in the county.

At San Diego a few days since a miner named Burns shot and killed one Jones of Silver City, Nevada, for having jumped a mining claim.

Facts from the Patent Office.

Number of patents issued by the United States Patent Office, to residents of the different States, Territories and foreign countries, from January 1st, 1875, to December 31st, 1875:

Leaving the actual number expired..... 1,323.

The *Scientific American* makes an analysis of the table, which shows some interesting facts. The geographical distribution of inventors to whom patents were granted in 1875, appears by it to be as follows:

To the six New England States there were issued 3,188 patents, being one to every 1,094 people.

To the seven Middle States (including Delaware, Maryland and West Virginia) 7,905, one to every 1,623 people.

To the nine Western States (including Missouri) 3,076, one to every 3,360 people.

To the 12 Southern States, 814, one to every 13,279 people.

To the three Pacific States, 437, one to every 1,699 people.

To nine Territories, 59, one to every 12,303 people.

And to the District of Columbia, 214, one to every 615 of population, being the highest ratio in the Union.

All the States and Territories have held their own, or made gains over 1874 in the number of their patents, save the following, which show losses: Alabama, Arkansas, Florida, Georgia, Kansas, Mississippi, Nebraska, Oregon, Vermont (for a wonder), and Dakota, Utah, Washington and Wyoming Territories.

New Hampshire and Nevada remained stationary, the former having 127, the latter 16 patents, the same as in 1874.

The principal increase was made in the following States: New York, 936; Pennsylvania, 390; Massachusetts, 340; Illinois, 164; California, 98; and the District of Columbia, 69.

The Rainfall.

As we have just passed through a time of liberal and general drenching, we compile from our interior exchanges a schedule of the total rainfall for the season to February 12th, at the places mentioned.

Colusa, Colusa county.....	12.85	inches.
Grass Valley, Nevada county.....	45.43	"
Petaluma, Sonoma county.....	18.15	"
San Rafael, Marin county.....	30.30	"

*And 67 inches of snow. †Up to Feb. 9th.		

The Dip of the Comstock.

Our attention has been called to a kind of pamphlet which has been widely distributed, and headed "The Great Comstock System of Mines," by W. Frank Stewart, in which the author appears to wish to convey to the public the idea that he was the first person who discovered the true course and dip of the Comstock lode. Now, the first report that we remember by any mining expert, on the Comstock lode, was made in October, 1859, extracts of which appeared in the *Sacramento Union*, November 10th of that year. In that report the lode is described as dipping to the eastward. In our issue of February 23d, 1863, we referred to this fact.

If Mr. Stewart knows anything of the history of the Comstock he will recollect when the one-ledge theory was started, in the snit of the Ophir & Burning Moscow, and what was then said about the dip of the lode. We do not understand Mr. S. when he speaks of the selvages and clay seams. The latter term is generally used by miners to represent a stratum whose normal position is horizontal. Mr. S. talks of a broad belt of porphyry, inferring, as we understand him, that the country back of the Comstock lode is composed of that character of rock. As Mr. S. professes to know something of lithology we should be glad if he would inform us to which class of volcanic rocks porphyry belongs—acidic or basic? We never heard any miner of standing say that the Comstock lode bifurcated in the way Mr. S. states.

If we mistake not Mr. S. published something in one of the Virginia papers about the telluride of silver forming a large proportion of the ores of the Comstock. The University of California and the Academy of Sciences would, we should think, be glad to get specimens of such ore from the Comstock lode. In Mr. Stewart's pamphlet this reference to the "theological structure of the Comstock lode" is probably a curious typographical error.

DEATH OF DR. LOGAN.—When the month of January closed we wondered why we did not receive our customary advice of the rainfall in Sacramento from our esteemed contributor, Dr. Thomas M. Logan. We were not long in doubt, for tidings came of the death of the gentleman whose life is so inwrought with the life of the State. He died on Saturday night last after an illness of three or four weeks. Dr. Logan was born in South Carolina, his father being a prominent physician. In 1828 he graduated from the medical college of that State, and in course of time entered into the practice of his profession at New Orleans, from whence he came to California in 1849, locating at Sacramento. Even in those early days, when everything in the State was in a chaotic condition, and few people cared to do anything that was not to be rewarded promptly with gold, the doctor began keeping the records of the thermometer and barometer, rainfall, health statistics, etc., which he carefully continued until his late illness, and which have been so valuable that his figures and notes have been extensively copied not only in the United States, but throughout Europe, and caused him to obtain a very enviable reputation. At the time of his death he occupied the chair of professor of hygiene in the medical department of the State University, was secretary of the State board of health, of which he was virtually the originator, and also secretary of the board of health of Sacramento; a prominent member of the State medical society, which he did much to reorganize a few years ago; president of the Agassiz institute of this city; an honorary member of the medical society of Vienna, etc. In 1873, at the 24th annual session of the American medical association, in St. Louis, he attended as a representative from California, and was honored by being elected president of the association. His love for science extended to its twin sister, art, to which he paid much attention. As a medical practitioner he was successful and popular, and in all his relations with society he was held in the highest esteem. His age was 68 years.

THE COCHRANE ORE FEEDER.—The Cochrane ore feeder, recently illustrated in the Press, is meeting with great success. Messrs. Hendy & Cochrane, manufacturers, No. 32 Fremont street, show us several letters from different parties using these feeders, in which they are highly praised. Mr. C. C. Belding, of Drytown, Placer county, says that he "does not see how it is possible for anything to work better than those he has in his mill." They are attracting considerable attention there. The 10-stamp mill is crushing 20 tons per day through a No. 6 screen. Mr. Aug. H. Schmahel, of Newcastle, Placer county, says: "The feeders work splendidly, and are just the thing wanted in all mills. In the first place I think more rock can be crushed by their use; in the second, they save screens; in the third, they operate so that the gold is saved better; and fourth, it saves wages. You are never bothered to get good feeders, for they are always right there on hand, and as long as you keep them full and properly set they will do their work."

SINKING on the main shaft of the Raymond & Ely mine was resumed on the morning of the 10th inst.

Hydraulic Gold Mining in California.

(No. 8.—Written for the Press by C. J. Brown.)

The Franklin Gravel Mining Company.

This company is a California corporation, with its principal place of business at the city of San Francisco. Its capital stock is \$2,000,000, in shares of \$100 each.

The present directors of the company, I believe, are J. D. Fry, O. F. Griffin, R. N. Graves, Jos. Sharon and C. A. Booth.

The ground owned by this company lies to the southwest, or down the channel from the Southern Cross, with the Bear River Hill and the Queen City claims intervening, (which latter aggregate a strip of ground about 400 feet wide,) and extends from the southeast rim rock to near Bear river, and is known as the Franklin claim; it has an area, I am informed by the Superintendent, of 45 acres. It was owned and worked for many years by Mr. Jas. Teaff, a veteran hydraulic miner of this place, who still retains an interest as a stockholder in the company, and who is now its superintendent. Mr. Teaff came here a young man in the prime of life; he was reared to a life of usefulness as a practical mechanic, and is a man of stern integrity, probity and honor, a steadfast friend of the laboring classes in all departments of industry, and, were I now to write his obituary notice for the future, I could not say less, nor possibly more than: "Here lies the earthly casket of a man who, in adversity as well as prosperity, rendered unto the laborer his hire to the utmost farthing." He is public spirited and sympathetically philanthropic, even to a fault; the needy and the unfortunate find in him a friend indeed, and he is ever on the alert to alleviate suffering and lighten the burden of the lowly and oppressed; he is an energetic worker and never flags in the prosecution of any enterprise he espouses, but, with nothing but zeal, pursues the course and line of work first determined upon, till its final completion. He is more a worker than a thinker, and being extremely self-reliant, is consequently more liable to err in judgment than fail from lack of energy. The mining interest of this district is, in great measure, indebted to Mr. Teaff for his constant exertions to demonstrate its great value and bring our bottom gravel mines prominently before the public at a time when by draining the top bench of gravel had nearly ceased, which has finally resulted in such an investment of capitals as to insure its complete development.

Mr. Teaff, with his partners, commenced work on the Franklin ground in A. D. 1854; afterwards becoming sole owner, he went forward and ran a gravel tunnel 1,700 feet in length.

I am informed by Mr. T. that this tunnel (which is now unused,) with its full complement, cost him the sum of \$55,000, and that prior to A. D., 1870, the claim had paid, for water alone, the sum of \$145,000. He estimates that up to that time there had been extracted therefrom the sum of \$300,000.

The Dutch Flat Blue Gravel Mining Company.

A company incorporated under the above name purchased the Franklin claim of Mr. Teaff in A. D., 1871, which, under the superintendency of Mr. Dorsey, of San Francisco, went forward and erected thereon a superb hydraulic rigging, consisting of 3,500 feet of iron pipe, constructed from No. 8 to No. 16 sheet iron. This pipe, which is yet an apprenticeship to the ground, is five feet in diameter at the head and 22 inches at the tail thereof, its pressure is given under a fall of 465 feet, and it has a capacity of about 3,000 inches of water. This company was, for numerous good and sufficient reasons, unsuccessful, consequently in 1875 the entire property fell into the hands of the Franklin gravel mining company, which thereupon contracted with Mr. Teaff to run a bed-rock tunnel six feet wide and eight feet high through the northwestern rim into the gravel bed. Mr. T. has completed 400 feet of the tunnel, at an expense of \$30 per linear foot, which is as cheap as any miner may expect to excavate a tunnel of that dimensions in the rock along this channel. The head of this tunnel is 68 feet below the surface of the rock, and 148 feet below the top of the gravel, giving an 80 foot gravel bank. A perpendicular shaft has been sunk through the gravel and part way into the rock, meeting an incline raised on an angle of about 80 degrees from the head of the tunnel. This work has all been done by hand power, and the tunnel, which debouches into the canon of Bear river, is run on a ten inch grade to twelve feet, and is a splendid piece of work. The head-sills for the flume were laid in the rock as the work advanced and a four foot flume will have been placed therein before the publication of this letter; 384 feet of similar flume, on the same grade, provided with three under-currents, has already been constructed from the mouth of the tunnel along the steep hillside, where, from the nature of the surface, Mr. T. was compelled to excavate a bed for it in solid rock. This company, when the pit is fairly opened, will require and use, if obtainable, from 1,000 to 1,500 inches of water.

In No. 3, published in the Press of the 11th of September last, I asserted that the deep channel crossed under the southern (more

correctly south-eastern) portion of this Franklin claim. No one familiar with the ground doubts the correctness of this assertion, consequently I assume that the head of this bedrock tunnel is at least 1,000 feet to the north-west of the center, and high above the bottom of the main channel which the claim covers, and the gravel which is to be washed through it lies along the inner slope of the rim rock dipping to the head of the channel, toward which it could be washed with great facility if the claim should be opened through a tunnel deep and long enough to reach the lowest depression in the rock. Such a tunnel could not be much, if any, less than 2,000 feet in length, and would cost, at present rates, the sum of \$80,000. The claim covers about 750 feet in length of the deep channel. No drifting has ever been done thereon, but the ground has been prospected by means of shafts, sufficient to justify us in saying that it is as rich as any situated on the Dutch Flat channel. The gravel—including a 40 or 50 foot stratum of trap slide—is about

enterprise is, at best, of but temporary use, and the expenses are too great when compared with the amount received; the greatest loss lies in the fact that in a short time the major part of all the capital invested becomes a dead loss; while on the other hand, a deep tunnel like the Cedar Creek, the Southern Cross, and the Polar Star companies are respectively completing, is a permanent improvement, and for all time till the mines are completely exhausted.

I have no doubt that eight or ten feet of the bottom of the bank where the company is now operating will pay better to mill than to hydraulic, but building a mill upon this high rim rock would be a repetition of the folly of Tom Jefferson—or some other man—who once built a wind-power saw mill on the summit of a high hill, and demonstrated the fact that the cost of getting his logs to mill exceeded the value of his manufactured lumber. I would be gratified to see the Franklin imitate the other companies I have mentioned and proceed to run a deep tunnel; if the area of its claim will

LOWER FALL OF THE YELLOWSTONE RIVER.

225 feet at the deepest, and will probably average on the whole 110 feet deep.

Whether any one claim located along this Dutch Flat channel will justify being worked at present, depends largely, in my opinion, upon its size and its special location, and the facility and rapidity with which the gravel and debris can be removed. The Franklin may hydraulic off a bench of the high wash along the rim with a highly satisfactory result, but it could be sluiced through a deep tunnel with greater ease and the dirt be used (as it is all greatly needed for such purpose) to help remove the heavy bottom boulders. In my opinion, if this company is justified in mining its claim as a separate undertaking, independent of any other company, it must have its justification upon the completion, in the first instance, of a deep bed-rock tunnel, long enough to tap the lowest depression in the channel, and from thence open up its ground from top to bottom.

I have no faith in the policy of washing a top bench with the view of obtaining capital to develop the bottom. The work done in such an

not justify, let it purchase the Queen City and the Bear River Hill claims adjoining the Franklin on the northeast, which will give it about 400 feet more in length along the main channel, and the Boston claim which adjoins on the southwest; though this latter claim covers little or none of the deep channel, it is, nevertheless, a valuable piece of ground, and would be of great benefit to the Franklin in the event of its working through a deep tunnel.

Dutch Flat, Feb. 14th, 1876.

The mills on Carson river are all running to their full capacity, and as there has been plenty of ore constantly on hand, no stoppages have been made on account of the snow blockade. There is plenty of water in the river, and no difficulty is experienced now, as there was earlier in the season, from the freezing up of the water-wheels.

LARRY CRONIN, the miner who was injured a few days ago in the Dayton mine in Virginia City, by being crushed under the cage, died of his injuries on Friday last.

The Yellowstone Falls.

At the head of the grand canon is the lower fall of the Yellowstone, which is 397 feet in height; at the foot of the fall the depth of the canon is 675 feet. The center of attraction is the lower fall, which is illustrated on this page. Prof. Hayden, in his "Geological Survey of the Territories," thus describes it:

"The river suddenly narrows to a width of only 100 feet and rushes over a ledge of trachyte, falling 397 feet to the bottom of the canon. The water at the edge of the fall is very deep and of a deep green color. Huge boulders thrown in are carried by the force of the current far out from the edge of the fall. When we approach the brink and look over into the abyss we begin to realize the littleness of man when in the presence of nature's grand masterpieces. Down, down goes the whirling mass, battling and writhing as the water dashes against the rocks with a noise like a discharge of artillery. Here and there a resisting rock is met with and the water rebounds, broken into myriads of drops, which throw back to us the sunlight resolved into its primitive colors. The bottom of the canon reached, the immense mass of water seems to dissolve itself into spray, and then recovering, it flows down the gorge an emerald-green stream, dashed with patches of white, heaving with furious waves the rocky walls that imprison it. Taken in connection with the varied tints of the canon itself, red, yellow, orange, white, the dark-green pines fringing the top, and the bright green of the spray nourished moss on the sides of the fall, we have a picture of almost unequalled magnificence and grandeur. It is a scene of which one never tires and in the description of which language fails."

RICH ROCK.—We were shown, to-day, a specimen of chloride ore from a lot of ten tons just reduced at the Manhattan mill, which was extracted by Louis Schoff from the Sagebrush mine, Yunklee Blade, two and one-half miles distant from Austin. The specimen is a special piece intended for presentation to the cabinet of the Society of Reese River pioneers, and is very rich, being all chloride and horn silver, and will probably assay far up into the thousands. The lot worked at the mill gave an average result of \$476 per ton, the first working \$2,064.14; second class, \$615.75; third class, \$210.50. The ore was discovered in the grass roots, while the discoverer was pulling sagebrush with which to build a fire. With such bonanza as this lying around loose right at our very doors, the Black Hills sink into insignificance.—Reese River Reveille.

JACOTINGA.—In the London Mining World of January 22d we find a report of the Don Pedro North del Rey mine, Brazil, in which it is stated that the loss of gold in working their vein stone jacotiga (micaceous specular iron ore, with which the gold is mechanically combined), was 18 per cent. of the original contents, the original gold contents being about \$46.50 per ton. The separation of gold from the jacotiga is a difficult process, much more so than when it is mechanically combined with pyritic matter. We have never met with any of this class of ore in any vein on this coast; at least one-third of the gold from Brazil has been obtained from that character of vein material.

THE FIRST SHIPMENT.—The Winnemucca Silver State says that the Eagle mill and mining company of Lewis district, near Battle Mountain, have made their first shipment of bullion. It consisted of two bars, valued at \$4,000. The company have had some trouble with the roasting furnace attached to the new mill. The Deference mine, owned by the company, has been reckoned among the best in Central Nevada, and it is undoubtedly entitled to that consideration. A year ago, while the mine was being prospected, a car load of the ore brought to the Humboldt reduction works by C. W. Frasier yielded over \$500 per ton.

GOLD IN ALASKA.—M. P. BORRY, collector of the port of Sitka, Alaska, in a communication to Secretary Bristow, dated January 18th, says: One member of a small party of prospectors arrived at Kobuk during the month of September and stated that himself and party had been mining on one of the branches of the Kenai river. They made from \$4 to \$6 per day, coarse gold; no bedrock reached. They could not state whether there were extensive diggings or not, as they had to leave on account of health.

MORE trouble is being experienced on the track of the Virginia and Truckee railroad at a point a short distance east of Fort Homestead, by the settling of the ground under the track. It is the same place at which so much trouble was had a month or two ago. Again they are filling in the sink with waste rock. The settling of the ground does not interfere with the regular traffic of the road.

A CYLINDER for the steamer Yosemite was successfully cast at the railroad foundry, at Sacramento, Friday. It is 57 inches in diameter and 11 feet stroke. It is the largest casting ever made in that city.

On Monday night Peter O'Neil was killed by a blast in the Champion mine, on White Pine mountain.

English Built Steamers for the Pacific Mail S. S. Co.

The mail contract between the government of New South Wales and the Pacific Mail company is for eight years, and the amount of the subsidy annually is £90,000. The company intends to place on the route three steamers—the *City of San Francisco*, the *City of New York* and the *City of Sydney*. Between Sydney and the Fijis, and New Zealand, English steamers will carry the mails, and the following extract from the *Illustrated London News* shows that these vessels are completed, and that one has sailed:

The dimensions of the *Australia* are: Length, 376 feet; beam, 37½ feet; depth from base line (bottom of floors) to spar deck, 28 feet 8 inches; depth of hold from top of floors to main deck, 19 feet; tonnage, about 3,000, British measurement. The engines, of 500 horse-power, nominal, working up to 2,400 horse-power, effective, are compound, with two cylinders of 62 inches, and one cylinder of 45 inches in diameter; stroke, 4 feet 3 inches. They take three grips of the crank shaft, instead of two, as is usual in marine engines, and the result is a steady, quiet movement, almost inaudible in the saloon, even when the engines are working at high pressure.

The sleeping cabins for the first-class passengers are of a very superior character, most of them being placed on the main deck, forward of the spacious dining saloon. A number of staterooms on the upper or hurricane deck are arranged for two passengers only, while a few are admirably adapted for families. They are covered by a light and elegant deck, affording an elegant promenade for passengers during the day-time, and projecting sufficiently over each side to provide an awning for the cabins and a roomy sheltered walk. The windows and venetian blinds, with which these cabins are fitted, must make them exceedingly light and airy. The dining saloon is very handsome, extending across the ship from side to side, with four tables running fore and aft the entire length. It measures sixty feet by thirty-eight feet, with sixteen inside ports, and is lighted and ventilated by a lofty, dome-shaped skylight, which is one of the most striking features of the ship. Contrary to custom, the saloon is placed forward of the funnel, thus escaping the smoke and heat from the engine-room. The *Australia* has accommodations for 164 first-class, 24 second-class, and 85 third-class passengers.

The *Australia* and her sister ship *Zelandia* were built especially for the Australia and San Francisco service by John Elder & Co., Glasgow. The *Zelandia* sailed from Plymouth for Melbourne on the 19th of December, and was spoken at St. Vincent, Cape de Verde island, on the 28th of the same month, having made the run in eight days and seventeen hours, being an average of 12 nautical miles an hour. She was expected to make the voyage to Melbourne comfortably in 43 days.

The South Chariot Mine.

The editor of the *Owyhee Avalanche* has made a visit to the South Chariot mine and speaks very flattering concerning it. He says: "About 32 miners are now employed in this mine, and the company's 10-stamp mill is being kept running on ore extracted from between the 6th and 7th, the 7th and 8th, and the 9th and 10th levels.

"Between the 6th and 7th levels they are now stoping at a point 450 feet north of the shaft, where the vein is from one foot to two and a half feet in width, well defined and producing splendid milling ore, with every indication of continuing as good up to the Minnesota line, 150 feet further north. This pay shute pitches down through the 7th, 8th and 9th levels at an angle which brings it within 115 feet of the shaft on the 10th level, where Superintendent Crutcher struck it by running a cross-cut some 24 feet from a drift which, for some unexplained reason, was run by a former superintendent through solid granite almost parallel with the ledge. On the 10th level the vein is larger and richer than in the levels above, the ore showing handsomely in silver interspersed with considerable free gold.

"From the foregoing it will be seen that in the South Chariot, north of the shaft, a rich ore body is known to exist in the shape of a trapezoid, whose upper and lower boundaries are 150 and 535 feet in length, on the 6th and 10th levels respectively. Allowing that the vein will average only one foot in thickness and reckoning 12 feet of solid quartz to the ton, we find that this body of ore will produce 10,552 tons, and, estimating that it will pay \$40 per ton (a low estimate), we have a net yield of \$422,080 from ore now 'in sight.' As this pay shute is found on the 10th level, as above stated, it is reasonable to presume it will also be developed in the 11th, and how much deeper, of course, no one can tell."

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

NOTICE.

Whereas, numerous persons have represented themselves as Agents of the FRYER PROCESS, the public are hereby notified that there are no authorized Agents. All business connected with the process must be transacted, until further notice, through the office of the FRYER NOBLE METAL MINING COMPANY, at Grass Valley, Nevada County, Cal.

I. ROBERT M. FRYER, Supt.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of all machinery and furnaces for the treatment of rebellious ores.
Office—439 Bush street, S. F.

MINING ENGINEER.

A Mining Engineer, with the best of best of references, thoroughly experienced in the opening and superintending of mines and mills, desires an engagement. Address, "MINING ENGINEER," MINING AND SCIENTIFIC PRESS Office, San Francisco.

No AGENTS are authorized to receive subscriptions for this paper at less than our advertised rates.

Hooker's Patent Direct Acting Steam Pump.

N. B.—Also manufacturer of Hooker's Deep Well and Double-Acting Force Pump. Received the Silver Medal awarded at the last Mechanics' Fair in San Francisco.

THE TURBINE.

Simplest, Cheapest, and Most Durable.

The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of mill remains the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.

Territory for sale outside of California, at reasonable rates and easy terms.
Mills built to order of the best material, and at the shortest notice, by Kimball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.
For further information regarding Mills or Territory, send for New Circular. Address,
A. H. SOUTHWICK,
P. O. Box 1385, San Francisco; or
P. O. Box 25, Oakland, Cal.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

WM. McCRINDLE, Manager, 22 & 24 Fremont St., S. F.

(Continued from Page 117.)

pump will be started into operation. Sinking the shaft deeper will be resumed as soon as practicable—probably day after to-morrow.

MEXICAN.—Sinking the winze below the 1465-ft level is making steady progress, the bottom still in fine appearing quartz.

MINT.—Putting in the several stations in the pumping compartment of the shaft is making steady progress. Sinking the main shaft is also making good headway. It is now down 1,015 feet.

MONUMENTAL.—The rock in the bottom of the shaft is quite hard, but blasts not well and admits of fair progress. The shaft is now down 75 feet. The sinking is being energetically pressed forward, and the shaft will soon have reached a depth at which it will be necessary to erect steam machinery. This it is the intention to do as soon as it is required.

NEVADA.—Considerable improvement is shown in the face of the main drift north, the streaks of low grade ore coming in wider and giving better assays.

NEW YORK CONSOLIDATED.—The east and west cross-cuts on the 800-ft level are each steadily advancing, with very encouraging prospects in the face of the west drift. The enlargement of the shaft is going steadily and rapidly forward.

NORTH CARBON.—The ore in the north drift is looking and promising finely, improving with farther advancement of the drift. A station is complete to open the 200-ft level, and sinking the main shaft deeper is resumed, as every development goes to show that only depth is required to find the ledge concentrated into a fine payable body.

NORTH CAROLINA VIRGINIA.—The pump station at the 630-ft level is completed and sinking the main shaft has been resumed. The bottom is in ledge material of a very favorable character, and it is confidently expected that the ledge will be cut by the shaft before reaching a depth of 1,000 feet, or 340 feet more than its present depth. The company has determined to press the shaft with all possible energy until a depth of 1,000 feet has been attained or the ledge struck; and then to open a number of levels at this same time.

OHIO.—Daily yield, 150 tons of ore. The ore breasts are all looking well and yielding ore of a good quality. Two mills, the Nevada and Empire State, are kept steadily at work crushing the ore, and had it not been for the snow and stormy weather interfering with the hauling of the ore, the Winfield mill would have been started up this morning. Clearing out and repairing the winzes and drifts below the 1600-ft level is making steady and favorable progress. The prospects in the east drift on the 1100-ft level are excellent.

ORIGINAL GOLD HILL.—Both raises in the south ore body continue in excellent ore, and the various breasts and stopes at the ore track level are looking finely. Ore extraction continues suspended owing to the dump being full and the roads in too bad a condition to allow of hauling the ore to the mill.

OVERMAN.—Sinking the shaft is making fair progress considering the hardness of the rock in the bottom. The prospecting drifts and cross-cuts, on the 1100-ft level, are all steadily pushed forward without any material change during the week.

RAN AND WATTS CROSS.—This is a double location, consisting of two claims, 2,000 feet in length, lying parallel with and adjoining each other, 450 feet east of the famous O. & C. shaft, Virginia City. The location is an old and very valuable one, with a fine looking ledge cropping out at the surface. Both claims are being conjointly worked by means of a three-compartment shaft, which is now being sunk on the division line between them. This shaft is now down 50 feet, and sinking is suspended for the purpose of timbering. Dr. James Delavan, a mining man of judgment and experience, is superintendent, and is pushing the work along industriously.

ROCK ISLAND.—Sinking the main shaft is making excellent headway. Prospecting the ore vein on the 650-ft level has developed no new features during the week.

SAVAGE.—This morning the water had risen to a point in the main incline 125 feet above the 1900 ft level, having risen yesterday 11 feet during the day. It is evident that the water in the incline has nearly reached the level from which the source springs, and is not therefore liable to reach a very much greater altitude. The pumps of the Savage and the O. & C. hoist the water at the rate of 26,000 gallons per hour, that being the full capacity of the pumps and water tanks. Designs have been drawn for large and powerful pumping machinery, which will probably be manufactured and erected in the shortest possible time.

SOUTH CONROCK.—Total length of cross-cut, 365 feet. The last 12 feet of it is in hard white quartz, heavy with sulphurets or pyrites of iron, and giving very fair assays in silver and gold. The drift passed through a thick and very favorable looking clay wall before encountering the solid ledge of quartz, which is evidently the main west vein which Superintendent Nelson has been drifting for so long. After passing through the clay wall, considerable water was met with, which increased rapidly with every foot of advancement, and has proven so troublesome the last five or six days, that very little progress has been made in drifting, the machinery having about all it could do to keep the water reduced. Some improvements are being made in this respect, however, and drifting can shortly be proceeded with.

SILVER NEVADA.—Sinking the main shaft is making steady progress, the bottom in excellent working ground. The south drift on the 1000-ft level shows no change during the week. The south drift on the 1250-ft level is steadily advancing, with no new important features to report. The north drift on the 700-ft level of the old shaft is also making steady progress, without change of interest.

SOUTH CARBON.—Clearing action has been made by the south drift mentioned in last week's report with the main ore stopes, giving good air circulation and an excellent outlet for the ore. The drift north from the upraise continues in high grade ore. Prospecting at all points goes forward systematically and effectively, and the dump is getting overladen with first-rate ore. Will start milling next week. At the annual meeting of the company, held last Monday, Mr. Morganthau, J. H. Helen, S. R. Palmer, J. P. Dyer and S. Heydenfeldt were elected directors for the ensuing year. S. Heydenfeldt was elected President, and A. K. Durbrow, Secretary. Sixty-two thousand five hundred and fifty shares were represented at the meeting.

SILVER HILL.—Sinking the main incline shaft below the fourth station level is making steady progress, the rock in the bottom working quite favorably. The work was commenced four or five days ago in the face of the main east drift on the fourth station level, but had to be again stopped on account of a strong increase in the flow of water. The water has decreased to a sufficient extent to again allow the men to resume work in the face of the drift this morning.

SILVER HILL.—The men again started up and the water drained from the bottom of the shaft. Sample of the ore taken from this ledge, recently struck in the bottom of the shaft, give average assays ranging from \$40 to \$200. No opportunity has yet been given for determining the width of the ledge and the extent of the ore body. Now that the shaft is again clear of water, some lively developments may be looked for. This ore vein is in an entirely new and unexplored range, and its further development is a matter of much interest to all the mines to the eastward of the Justice and Woodville, and the results will be anxiously looked for by many outsiders, as well as the direct stockholders of the Successor. The north cross-cut on the 550-ft level is also showing some very favorable looking quartz and ore. No change in the main west drift on the 550-ft level.

SULLIVAN.—The cross-cut east from the south drift is now in 45 feet, and being pushed ahead both night

and day, working three shifts of hands. The material being passed through is the same splendid looking vein matter heretofore mentioned. Some hard streaks are met with, but generally speaking it is softer and more favorable, with better ore streaks and indications than have yet been encountered at this level.

UTAH.—The water has been drained from the shaft to a point a little below the 500-ft level, and is being gradually reduced at the rate of 13 feet per day. The shaft is found to be in an excellent condition, so far having no need of any repairs whatever. The repairs to the drifts on the 400-ft level are gradually progressing, although it will take some time yet to put that portion of the mine in as good condition as it was before the destruction of the hoisting works.

UNION CONSOLIDATED.—The face of the cross-cut from the north drift on the upper tunnel level is still in clay and ledge material mixed. Sinking the winzes below the 1300-ft level is steadily progressing, the bottom of both in quartz and ore.

WEST BELCHER.—The steam hoisting machinery for this mine arrived yesterday, and will be put into working position as soon as practicable. As we have before stated the company have made full arrangements, under contract with the Overman mining company, to use the old Overman shaft, therefore the hoisting works are being erected at that shaft. By this means the West Belcher can and will be opened and worked in the most advantageous manner possible, at whatever cost a design from the shaft of 400 or 500 feet will be required to reach the fine ledge of pay ore already developed in the upper workings.

YELLOW JACKET.—The several cross-cuts and prospecting drifts on the 1940-ft level are steadily progressing in favorable looking material. Otherwise nothing new or interesting to report.

ELY DISTRICT.

RAYMOND AND ELY.—Pioche Record, Feb. 6: During the past year from 13,644 tons of ore have been extracted from the mine which has pulped \$75 per ton. Since the 1st of January quite a number of changes have been made in regard to working and extracting of ore. Numerous contracts have been let, some on the Burke & Creole which will return dividends to the company, it heretofore being almost dead work in these companies. The superintendent, D. M. Tyrrell, has let a contract on the main shaft, called the Lighter shaft, to several parties, the contract being to sink 125 feet at the rate of \$45 per foot, the company furnishing tools, timbers and agresting to keep the shaft dry. The contractors will start about Monday; in the meantime the company are busily engaged in cutting out for a station tank, which will be completed and everything in order by that time. The pump has now only to run 16 hours out of 24 to keep the shaft drained. The flow of water has not increased lately and the pump is working to the satisfaction of every one. The ore on the 10th level seems to be the best that has ever been struck in the mine, pulping \$150, so that the shipments of bullion for the month of February will largely exceed those of January.

ALPHE.—During the past week work has been continued on this mine with the same regularity as formerly. Work on the lower level is progressing slowly, owing to the hardness of the ground; progress, however, is satisfactory. In the upper portions of the mine the different drifts look well and continue to improve, they extracting from the same an average of 16 tons daily.

AMERICAN FLAG.—During the past week work has been commenced on this mine, a small number of men being placed on it, the time that it was idle being consumed in placing the machinery and hoilers in proper order. This has been completed and the work will go on as usual. We heard something of a strike being made immediately on the resumption of work, but could not trace it to any reliable foundation. The mill is expected to start in a very short time.

MEADOW VALLEY.—Owing to the recent storms the building to cover the hoisting works has not been covered over or planked up yet, but if the weather keeps as pleasant as has been for the last few days, before our next report we will see the things in proper shape. Work is still continued by chloriders. On the 1200-ft level running the north cross-cut, which is being advanced rapidly, the ore of a very fine and very satisfactory character and working well at the Newark mill.

PROBIE.—On the 1000-ft level the vein continues to gain in size and strength. The filling is pure quartz with seams of metal assaying well; the ledge, however, taken as a whole, gives assays of \$20. The formation is much more favorable and an early and substantial improvement is expected. Nothing new in the other workings.

PROBIE WEST EX.—Although no work is being done on this mine, the advertisement in yesterday's Record shows that the recommencement of work is not far distant, as the company is settling up back indebtedness for the purpose of taking a fresh start. Mike Holland now has charge of this mine.

PROBIE CONWAY.—The company is now working two shifts on the main shaft, running night and day. The shaft is now down in the neighborhood of 50 feet, and is just getting into vein matter, there being occasionally rich bunches of ore throughout the shaft. Are sinking at the rate of two and one-half feet per day.

ANTILES.—The main shaft is down 190 feet and the ground grows more favorable. The cross-cut will be commenced for the ledge at an early day.

GET THE BEST.—From all we can learn there is no better life insurance company doing business here than the **MUTUAL BENEFIT INSURANCE Co.**, of Newark, New Jersey. Its assets are over \$31,000,000. It is represented on this coast by Mr. James Munsell, Jr., whose office adjoins our own, at No. 224 Sansome street, San Francisco. Some of the best business men on this coast are carrying policies taken out for large amounts through Mr. Munsell, who has been the gentlemanly and active agent of the company for some years. We would call the attention of readers to the new feature of accelerated endowment policies issued by this company only, as mentioned in their advertisement on another page, and fully explained in their circulars, which will be sent free on application. Under the "Accelerated Endowment Plan," recently originated by the Mutual Benefit Co., the date of payment (maturity) of all kinds of policies is considerably hastened ("accelerated") by the surrender of the dividends to the company from year to year, and ordinary life policies mature, and the amount of the insurance paid to the member during his lifetime. The only insurance journal on this coast, the *Pacific Coast Review*, speaks of this company as follows:

"A faithful and economical management, the Mutual Benefit Life Insurance company, of Newark, N. J., has a record equal to any company in America. Its dividends paid to gross premiums received, have been larger than those of any other company for the past ten years, and its average ratio of expense of management to income, since its organization, only amounts to eight and 76-100 per cent. It is purely mutual, dividing up the surplus and profits with the policy-holders. It is a sound and reliable company, under judicious management, and entitled to the full confidence and liberal patronage of the public."

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C. Feb. 15th, 1876.

FOR WEEK ENDING FEBRUARY 1ST, 1876.

DIRECT ACTION STEAM ENGINE.—William C. Wilcox, S. F., Cal.

ROAD SORAPER.—Robert A. Haw, Eureka, Cal.

CARPET CLEANER AND BEATER.—Chas. Elsasser, S. F., Cal.

BALE TIE.—Thomass Bailey, S. F., Cal.

British Patents for Pacific Coast Inventors.

Following is a list of inventions patented or protected by provisional specifications in England, by inventors in the Pacific States and Territories, from July 1st to December 31st, 1875:

ELECTRO-MAGNET.—W. L. Powelson, S. F., Cal.

OVERSEAM SEWING MACHINE.—J. L. Boone, S. F., Cal.

PREPARING FIBER.—C. C. Coleman, S. F., Cal.

PRINTING PRESS.—A. E. Redstone, Oakland, Cal.

SHIP'S TABLE.—E. P. S. Andrews, Havilah, Cal.

Canadian Patents for Pacific Coast Inventors.

Following is a list of inventions patented in Canada by inventors in the Pacific Coast States and Territories, from July 1st to December 31st, 1875.

POCKET-FASTENED PANTS.—J. Greenbaum, S. F., Cal.

SNOKE CONSUMER.—W. L. Powelson, S. F., Cal.

LOCK.—H. Rogers, Eureka, Nev.

HYDRAULIC JACK.—E. Biddle, Carlin, Nev.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

PORTABLE CARPET BEATER AND CLEANER.—Chas. Elsasser, S. F. This invention is a machine which is adapted for heating and cleaning carpets upon the floor without taking them up. It consists of a box, which is divided horizontally into two compartments. The bottom of the lower compartment is open, and a spring beater is placed in it, so as to be operated by a friction wheel which is rotated by pressure against the floor as the box is moved along. A suction fan is arranged to draw the dust which is raised by the beater into the upper compartment or dust chamber. The beater is composed of a number of parallel bars placed at a short distance apart and secured together by transverse bars on the upper side. This beater is placed across one end of the box at its bottom, and has a strong metallic stem extending upward from its middle and passing through a guide in the lower compartment. The upper end of the stem is hollow, and a strong spiral spring is placed in the hollow or cavity. A screw regulates the tension of the spring and the force of the blow. A shaft passes across the box, and upon it is a cam, which, when the shaft is rotated, strikes a projection or tappet on the stem and lifts the beaters, while the spring drives them back against the carpet when the cam leaves the tappet. The entire power for driving the machine is derived from the pressure upon the machine as it moves over the floor. A fan draws the dust into the upper box. The lower edges of the box are suitably packed to prevent any dust from escaping from the lower compartment. This machine will run over a carpet like an ordinary carpet beater, and will beat and sweep it clean without removing it from the floor. By using this machine once every two or three days upon a carpet it can be kept perfectly clean and free from dust without the disagreeable necessity of occasionally taking it up and sending it away to be beaten and cleaned.

TREATING ORES.—Eames & Patchen, San Francisco. This is an improvement on the Patchen process, which lately attracted considerable attention. When ore pulp is treated in iron pans with a chloride of copper, the iron of the pan precipitates the copper so that its effect upon the gold and silver contained in the pulp is lost. To remedy this difficulty Abel Patchen secured a patent in 1874, in which he claims the process of treating the pulp in a copper or wooden vessel before introducing it into the iron pans for amalgamation, thus allowing the silver to be chloridized before it enters the iron pan. These inventors have discovered, however, that by using a certain substance they can chloridize the metal contained in the pulp, directly in the iron pans, without the necessity of providing an extra vessel for the treatment of the pulp. They also claim

that by having the peculiar substances in the iron pan, the effect of the iron pan or the iron salt is neutralized so that little or no copper will appear in the amalgam; although the use of these chemicals enables these inventors to treat the ore chemically and without unfavorable results in an iron pan, they claim that they can produce superior results both in the quantity and fineness of the bullion by using them in the wooden or copper vessel claimed in Patchen's patent, and when the wooden or copper pan is already in use, they shall preferably use this process as being the most successful; but when the iron pans only are in use they will use the chemicals in the iron pan.

ATTACHMENT FOR RAWHIDE FULLING MACHINE.—Herman Royer, S. F. This is an improvement on a previous patent for a rawhide fulling machine, by the same inventor. It consists in an automatic belt shifting device, by which the inventor is enabled to run the machine in one direction for a sufficient length of time and then reverse it, this process continuing automatically until the leather is finished. The machines are usually operated by belts, but gears or friction coupling could be used, and the action of the machines still be automatic. The machine turns in one direction until a lever has passed the center and fallen over so as to shift the belt to the other pulley, when the whole mechanism will be moved in the opposite direction. The inventor claims the belt shifting device for the purpose of making the operation continuous and automatic, in combination with the rawhide fulling machine operating to twist the leather alternately in one direction and the other.

General News Items.

SERVIA is determined on war.

SENATOR SHARON has gone to Washington.

AND now they have unearthed an opium ring.

THE new iron furnace at Chico has been started up.

Big Guns and their Cost.

Just at present there is a mania in Europe for the manufacture of enormous cannon. One would think that several of the great nations were trying to see which can bring out the biggest gun. When the English 81-ton piece was successfully completed, it seemed likely to hold the field for some time without a rival; but before three months have elapsed we find that Italy has ordered four 100-ton guns from Sir William Armstrong, and that Krupp, in Prussia, "has in hand" (figuratively speaking, of course, though Krupp is a giant in a business way at least) a monster of 124 tons. Of course John Bull does not mean to be outdone, and it is announced in the English journals that "the authorities at Woolwich are prepared to commence a gun of 160 tons as soon as permission is granted."

The 81-ton gun has cost \$75,000, and the price named for the "Newcastle infants" of 100 tons for the Italian navy is \$120,000 each. We have not seen it stated what the Krupp monster is to cost, but it will probably be \$150,000 or more.

The testing of these guns, to say nothing of their use in actual service, adds not a little to this enormous expenditure. Every time the 81-ton piece is fired, it blows \$125 into the air, 240 pounds of powder and a projectile of 1,260 pounds being the charge in the first trials. In some of these rounds, 250 pounds of powder and a 1,465-pound shot were used. It is now proposed to increase the bore of the gun from 15½ inches to 16 inches, after which operation the charge will be proportionately augmented.

The Italian guns are to fire projectiles of 1,860 pounds each, while the Krupp cannon will send a ball of 1,040 kilograms, or about 2,300 pounds, through the air; how much powder is to be used in doing it we are unable to say. One gets, however, a new idea of the power of gunpowder when he learns that a few hundred pounds of it can propel a missile of more than a ton's weight over a distance of several miles. In the case of the 81-ton gun, the shot of 1,260 pounds left the muzzle with a velocity of 1,400 feet a second, and a momentum that would carry it through 20 inches of iron plating at a range of half a mile.

The *Dulius*, for whose armament the four 100-ton Armstrong guns are intended, is described as being the most powerful iron-plated frigate ever yet devised. She is to be armored with plates 19 inches in thickness, and moved by engines of 7,000-horse power.

Iron Rust a Cause of Fires.

An English writer asserts that where oxide of iron is placed in contact with timber, excluded from the atmosphere, and aided by a slightly increased temperature, the oxide parts with its oxygen, is converted into very finely divided particles of metallic iron, having such an affinity for oxygen that, when afterwards exposed to the action of the atmosphere from any cause, oxygen is absorbed so rapidly that these particles become suddenly red-hot, and, if in sufficient quantity, will produce a temperature far beyond the ignitable point of dry timber. Wherever iron pipes are employed for the circulation of any heated medium (whether hot water, hot air, or steam), and these pipes are allowed to become rusty, and are also in close contact with timber, it is only necessary to suppose that under these circumstances the finely divided particles of metallic iron become exposed to the action of the atmosphere (and this may occur from the mere expansion or contraction of pipes), in order to account for many of the fires which periodically take place at the commencement of the winter season.

ELECTRIC WHISTLE.—M. Lartigue, in charge of the electric service of the Northern railroad of France, has recently described a mode of warning the engineer of a locomotive approaching a station that the track ahead of him is already occupied. M. Lartigue states that the apparatus has been in use for more than a year, and has already prevented several possible accidents. It consists essentially of a piece of wood about two yards long, covered by a plate of copper which is included in the electric circuit controlled by the operator at the nearest station. The plate is raised about four inches above the level of the rails and placed between them. When the locomotive passes over this contrivance, a brush of metallic wires which it carries is pressed smartly against the plate and closes the circuit on the locomotive, bringing a soft iron magnet into contact with its armature, and thereby opening the valve of a steam whistle, which continues to sound until shut off again by the engineer. The principal objections to the contrivance seem to lie in the facts that it requires the previous action of a telegraphic operator, and operates only in the vicinity of stations.

SUBSTITUTE FOR THE SAND BOX ON LOCOMOTIVE ENGINES.—We see that Mr. W. Miller, the locomotive superintendent of an English railroad, has been experimenting on the use of hot water from the boiler, instead of sand, as a means of promoting adhesion on railroads. His experiments have convinced him that were his apparatus applied to locomotives it would entirely supersede the use of sand, for according to Mr. Mole-worth's rule he gains 350 pounds per ton on each coupled wheel during frosty or "greasy" weather. Mr. Miller would have patented his apparatus had he not discovered that a similar idea was registered many years ago.

The Simplest, Cheapest, Most Effective and Durable

Power Drill is the New

"CALIFORNIA" ROCK DRILL,

MANUFACTURED BY

HAWKINS & CANTRELL, San Francisco, Cal.,

AND SPECIALLY DESIGNED TO MEET THE REQUIREMENTS OF MINERS ON THE PACIFIC COAST

Manufacturers of Files of every Description

Nos. 39, 41 and 43 Richmond street,

Philadelphia, Pa.

Sold by all the principal hardware stores on the Pacific Coast.

18v25.1y

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes: Tarrad Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBES & CO.,

820 611 and 613 Front street, San Francisco

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim.

Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

BLAKE'S PATENT STEAM PUMP

Over 8,500 in Successful Use in the United States.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supls. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

TREADWELL & CO.,
San Francisco,
Are the only Agents for sale of these
Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)
Our new Mining Engine is built from plans and specifications of several of our most successful MINING ENGINEERS, and the result is the most complete

Double Drum Hoisting Engine
Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

Mutual Benefit Life Insurance Company,

NEWARK, N. J.

Assets, January 1st, 1876, - - - \$31,085,011 11

LEWIS C. GROVER, Pres't. JAMES B. PEARSON, Vice-Pres't.
EDWARD A. STRONG, Sec'y. BENJ. C. MILLER, Treas. B. J. MILLER, Actuary.

The following is a summary of the business of this Company, from May 1, 1845:

Total Receipts,	- - - - -	\$81,149,507 76
Paid Losses and Endowments,	- - - - -	19,284,541 48
" Dividends or Return Premiums,	- - - - -	19,224,524 15
" Surrendered Policies,	- - - - -	4,284,344 82
" Expenses—Management, Commissions, Taxes, etc.,	- - - - -	8,167,913 05
The Ratios are:—		
Expenses, (excluding taxes,)	- - - - -	8.60 per cent.

These results are more favorable to the insured than those presented by any Company in the World.

ALL KINDS OF APPROVED POLICIES ISSUED.

Dividends paid annually, or they can be applied on the Accelerative Endowment Plan, as ORIGINATED BY THIS COMPANY, to which particular attention is called.

ACCELERATIVE ENDOWMENT PLAN.

The plan is intended to meet the wants of those who wish protection for their dependents in case of premature death, and at the same time make a wise provision for themselves in the event of surviving the productive period of life.

The plan proposes that instead of using dividends in reduction of the annual premium, the insured may, at his discretion, pay his premium in full in cash, and surrender his dividends to the company. In consideration of this surrender, the company will agree to pay the sum assured when the policy holder shall have attained a certain age, or at his previous death, instead of at death only, thus enabling him to procure an Endowment Policy at the usual rates charged for policies payable at death only.

If the policy is already an Endowment, payable at a given age or previous death, the surrender of the dividend will enable the company to agree to pay the policy at a still younger age.

Advantages of the Accelerative Endowment Plan

Over any other yet offered to the public, will be apparent when the following features are considered:

It can be applied to any policy, whether "Life" or "Endowment," to old business as well as new, where there is no premium-loan, or where the existing premium-loan shall be paid off.

It enables one to obtain an "Endowment" policy at the usual "Life" rates.

The expenses incident to this form of "Endowment" insurance being no greater than in case of "Life" policies, its superiority to the old style of Endowment insurance will be readily perceived.

It not only has the effect of constantly reducing the age at which the company will agree to pay the policy, but also, every dividend so applied becomes itself the source of future savings, thus causing the dividends to increase much more rapidly from year to year than would be the case if they were used in payment of the annual premiums.

The assured can, in any year, apply his dividend in payment of premium, and allow the time at which the policy matures to remain as at the previous year's settlement.

As each dividend is surrendered, the company will make a positive agreement as to the time at which the policy will be paid, and the amount payable at such time.

It at any time the assured becomes disappointed or dissatisfied with the plan, he is at liberty to use his future dividends in payment of premium, and to retain all the advantages accruing from the surrender of past dividends.

If at any time the party should be unable or unwilling to continue payment of premiums, the company will, within three months from the date of lapse, allow the equitable value of the policy in paid-up insurance.

The Mutual Benefit Life Insurance Company issues Policies insuring the lives of healthy persons residing in any part of the United States.

VOLUME XXXII
Number 9.

Pump Manufacture in San Francisco.

In the manufacture of heavy pumping machinery the artisans of San Francisco no doubt excel those of any other city in the Union. The requirements of the deep mines of this coast are such as to call forth all possible ingenuity to overcome the great obstacle of water. The pumping machinery on the Comstock, all of which was made by the foundries of this city, is probably unequalled in the world; and yet, with all its strength and power, in some cases it is next to an impossibility to keep the mines free of water. Every now and then a body of water breaks in that tasks to the utmost all the pumping appliances at hand, and it is only by incessant, steady work that it is overcome. The manufacture of pumps of all sizes and kinds, therefore, has become a specialty of California machinists, and they now turn out from their shops pumps which are adapted to any special class of work, from the small pump for household purposes to the ponderous steam machinery for draining deep mines. Ingenious mechanics, who have made pumping machinery a life study, are continually at work inventing and improving in this direction, until it would seem as if perfection had been reached and there was no room for a step in advance. Occasionally, however, a lucky idea strikes some one, and some advantage over previous methods is gained.

We saw this week at the San Francisco steam pump works, on Beale street, a pump which has been constructed for the Bay sugar refinery, the first of its kind which has been made. It was designed by W. C. Wilcox, one of the proprietors of the works, and is intended specially for pumping molasses, syrups, coal tar, quicksilver, or any heavy liquid substance, although it will pump water as well. It is not an improvement, but a new invention. There are four slide valves in the ordinary place that poppet valves would be, each end of the valve in a V groove. The valves are handled by two little independent steam cylinders, and so arranged as to produce an instantaneous reversion of the valves at the instant steam is reversed in the engine, leaving clean wide unobstructed openings exactly at the proper time for action. The two small cylinders operating the valves receive their steam from alternate ends of the main cylinder and at the residue of the stroke of the piston. The instant steam enters into the main engine at one end steam enters into the two small cylinders and reverses the valves, and vice versa.

The valves work instantaneously with no noise and no lift. The opening of the valve seats is not obstructed at all by the valves being over it. The small cylinders are fastened on the end of the valve chamber of the pump by yoke connection. When the main engine exhausts the small cylinders alternately exhaust, and they take steam at the time the main cylinder does. The steam pipe connection between the cylinders is quite simple and unobtrusive. This pump seems admirably adapted to the purposes for which it is intended.

At these same works they are now making a number of different sized pumps, slide valve, deep well, poppet valve, etc. They employ from seventeen to twenty men, working principally on pump manufacture. They are principally occupied in the manufacture of the San Francisco steam pump, which was successful at the late trial of steam pumps at the Mechanics' Institute fair and won the gold medal. This is sometimes called the Wilcox pump, from its inventor, but should not be confounded with the Wilcox water lifter, a totally different thing and patented by another inventor. The success of the San Francisco pump at the competitive trial has had the effect of bringing a large number of orders to the manufacturers and of very effectively aiding in introducing a new and valuable improvement. They are now filling several mining orders and are prepared to contract to put up mining or irrigating works of any magnitude.

At the works can now be seen a pumping en-

gine designed by Mr. Wilcox for the artesian well of the Palace hotel. It stands on end over the well, the pump being lowered 100 feet in the well. The pump can be let down to any required depth and the engine placed vertically over it. Pumps of this class are made to suit any diameter of well. In this case the water is to be raised by a single lift to the top of the building, about 250 feet in all, and the pump is constructed to

Screw Cutting Machinery and Tools.

We illustrate on this page several forms of screw cutting tools, such as are manufactured by the Wiley & Russell manufacturing company, of Greenfield, Mass. Figure 1 is a No. 40 bolt cutter and nut tapper, fitted with seven sizes,

FIG. 1. BOLT CUTTER AND NUT TAPPER.

deliver 15,000 gallons per hour. The engine stands on two handsome fluted columns, and is arranged so that in case the pump should get out of order the engine can be swung around from the top of the well to one side. This piece of machinery is being neatly con-

structed and will be in keeping with its aristocratic surroundings. The San Francisco steam pump works, although only recently established by Messrs. Wilcox & Co., is doing quite a good business. They make a specialty of machinery for hand-

FIG. 2. BOLT CUTTER AND NUT TAPPER.

structed and will be in keeping with its aristocratic surroundings.

The San Francisco steam pump works, although only recently established by Messrs. Wilcox & Co., is doing quite a good business. They make a specialty of machinery for hand-

revolve. This machine is designed to satisfy such a want, and cuts well for straight or crooked work. The dies are held separately in collets. A strong vise holds the bolts or nuts, and a tap chuck is fitted to the same

FIG. 3. THE LIGHTNING SCREW PLATE.

ling water, although they are prepared with proper tools for doing any class of machine-shop work. They are now building a hand pump of peculiar construction, with valves so set that any ordinary person can take them out and replace them with ease. Mr. Wilcox is a methodical and painstaking inventor, and we are glad to be able to record the successful introduction of his inventions.

The steam hoisting works for the development of the West Belcher mine are being put in working position, at the old Overman shaft, as fast as possible.

upon the work is caught and drained into a basin in the bed piece, under the die holder. It is, in all respects, a carefully and thoroughly made machine; nothing is slighted, but all the parts are made strong and handsome, and dies and taps are of same quality as those furnished with other machines by the same manufacturers. Not only dies and taps, but every part can be duplicated promptly to order.

Figure 3 is a representation of the lightning screw plate. The chief feature of this invention is that the die does its work in a single cut, thus forming the screw thread at once, instead of by several trials, as is the case with the implement in ordinary use. In order to compensate for wear the die is capable of proper adjustment, so that it will keep its size with accuracy until used up, or over a long period of constant employment. It is stated that although it finishes its work at one cut, its operation is easier than the first trial with the common plate. With it a man can cut one and a half inch bolts without help, say three threads three inches long, one in three minutes. It is claimed that this invention will accomplish five times the work possible with any other screw plate. The threads are cut neatly and sharply into the bolts, and not, as is frequently the case with the common tool, jammed out of their iron so as to raise the threaded portion above the normal surface, thus impairing the accuracy and regularity of the operation. The dies allow of nuts and bolts for different purposes being made to fit together tightly or loosely, as desired. When worn out they can be replaced, the plate and collets remaining good. The articles threaded need not be matched and kept together, as they always correspond without being tried or fitted. The collets holding the dies have guides, as shown in the engraving for starting bolts true, though, when it is desirable to cut close under the heads of the latter, the face side is used. The design of the plate combines ample strength with remarkable lightness, and in quality, style and finish, the device appears to be an excellent tool. These tools may be seen at the agents, in this city, Messrs. Dunham, Carrigan & Co., 107 to 111 Front street.

A BOUNTY FOR STEAM POWER.—Mr. Hart, of Colusa, has introduced a bill "to encourage the invention of a machine as a substitute for horse power." It seeks to appropriate \$15,000 as a bounty to any citizen of the State who shall invent, and, after two years' continued trial and use, shall produce a machine propelled by steam or other motive agent, the object of which is a substitute for the use of horses or other animals on the highways or farm. The test of successful use shall be that any machine or locomotive entering the lists to compete for the bounty shall successfully plough at least 1,000 acres of land, as well and at a cheaper rate per acre than the same can be done with horses or other animals, and shall perform a journey of at least 200 miles on a common road in this State, propelled by its internal power, at an average rate of at least four miles per hour, working time. It must be of such construction and width as to conform with or run in the ordinary track of the common dray or truck now in use.

On the Ophir mine the main east drift on the 1600-ft level has been cleaned out and repaired to the face, and is again being extended to the eastward, cutting good milling ore some 150 feet further north than any that has yet been found in that portion of the mine. This is certainly a very favorable indication, proving, as it does, the extension of the ore body northward on the lower levels. The southeast drift on the 1100-ft level is being steadily advanced, the face in low grade ore. The prospect of yet finding an upward continuance of the ore bodies by this drift still further to the eastward is growing more encouraging every day.

LATE reports from Sawyer's Bar say the snow storm of last week deposited about six feet of snow in the Salmon River mining section, and the snow is very deep on the trail leading to Sawyer's Bar.

A new east body of rich ore has been opened in the Belcher mine which promises a large yield. The ore is rich in gold, the gold veins largely predominating over that of the silver.

CORRESPONDENCE.

The Fryer Process.

EDITORS PRESS:—The great interest which in all mining circles of this coast is presently felt in the Fryer process will justify my offering a few remarks on the subject. From the description given in the *SCIENTIFIC PRESS*, it appears that only atmospheric air, and perhaps steam, applied at a high temperature, are intended as roasting agents. This plan would, after the old style of roasting, be in contradiction of the well-known chemical affinities of silver. If sulphur were the only base admixture to silver ore, the roasting or desulphurizing of silver ore would be as simple as the burning of limestone or the desulphurizing of cinnabar; sulphur and silver part completely in a high temperature when oxygen is admitted. But arsenic and antimony, which are, besides sulphur, present in nearly every kind of silver ore, cannot be separated from silver merely by air and heat; they will on the contrary form arseniates and antimonates of silver, which are more refractory against amalgamation than the original combinations. For the roasting of silver ore salt is therefore generally employed with the view to separate these arseniates and antimonates by forming on one side chloride of silver, which has the desirable quality to amalgamate easily, far easier than metallic silver; and on the other side chlorides of arsenic and antimony, which are volatilized.

These facts, however, are so well known that I do by no means suggest—as the *Mining and Engineering Journal* rather unkindly does—that Mr. Fryer should not be perfectly aware of them. I would sooner suppose that Mr. Fryer's plan is a different one. There is in Sweden a most curious roasting process for copper ore used, by which the copper is concentrated in the centre of the single pieces of ore. An experiment not less curious can be made with silver ore. Heat a piece of silver ore in a common blacksmith fire to a red-hot temperature and plunge it into cold water: there will then be numerous drops of metallic silver found on the surface. I do not know what percentage of silver and gold can be separated in that way, but I almost believe that Mr. Fryer operates on the same principle. Some reporter, admitted to the works, mentions that he saw the burned ore covered with little drops of silver, by which I am led to believe that the unknown part of the Fryer process consists in dropping the red-hot mass of ore out of the furnace into a tank of water.

But whatever the treatment of the ore may be, it seems beyond doubt that a chloridation is not the object of the Fryer process and that silver and gold are to be separated in a metallic state. The probable results of the new method will then be the following:

1. Metallic gold amalgamates easily and the process will for gold-quartz most likely be successful.

2. Metallic silver amalgamates so very slowly that the little drops of silver may offer serious difficulties to amalgamation.

3. As the furnace is evidently intended for a great heat (which the suggested operation indeed requires) the process will do best for such ore as is not liable to smelt; while ore containing a certain amount of antimony, lead, copper or some other easily fusible metal, might be more or less melted in the furnace, by which the crushing as well as the subsequent amalgamation would become either impossible or very imperfect.

THERE is a lively discussion at San Jose whether the road to the site of the Lick observatory, on the summit of Mount Hamilton, shall be built by Chinamen, as the contractor to whom the work was awarded can hardly keep in the terms of the contract without employing cheap labor. The white workmen, many of whom have come from long distances in hope of a job, are naturally disgusted with the idea, and Mr. Lick has sent a dispatch to San Jose to the board of supervisors of Santa Clara county to the effect that if a Chinaman was employed in the construction of the Mount Hamilton road they would not receive a dollar from him.

SINGULAR CAUSE OF DEATH.—A woman residing in Albany county, N. Y., awoke one night lately with a severe headache, and, taking a bottle of salts from a stand near by, applied it to her nose occasionally. She soon fell asleep, and on awakening in the morning found that she had retained the bottle in her hand, and that the salts had drawn a blister on her thumb, which had covered the mouth of the bottle. In a short time inflammation arose, gangrene set in, and in spite of every effort to stop its progress her entire system became poisoned so that she died.

THE CENTENNIAL.—Mr. George Bancroft expresses the belief that the coming Centennial exhibition will in every respect excel any international exhibition heretofore given. He thinks it will drive away hard times and encourage immigration to an astonishing extent. Mr. Bancroft thinks the next presidential campaign will be the most exciting one of our history.

Amendments to the Coinage Act.

The following is the full text of Mint Director H. R. Lindermann's letter to the Secretary of the Treasury, recommending important amendments to the Coinage act:

"I have the honor to recommend for your consideration, and such action as you may deem appropriate, the repeal of so much of section fifteen of the coinage act of 1873 as makes the trade dollar a legal tender at its nominal value for any amount not exceeding five dollars in any one payment. When the issue of this coin was first proposed, it was not intended to be a coin for circulation in the United States or legal tender in payment of debts, but simply an agent in our commerce with foreign countries, particularly China. It appears to have been inadvertently made a legal tender by being incorporated in the section of the coinage act prescribing the weight and legal tender of the small silver coins. At the time of the issue of the trade dollar (1873) its bullion value was slightly more than its face value, and no inconvenience was experienced until since the market decline which has taken place in the value of silver. Its bullion value is now about 94 cents in gold. Adding to this the cost of coinage, one and one-fourth per cent. on its nominal value, gives to the depositor for trade dollars a profit of four and three-fourth per cent., provided he is able to use it at par. In consequence of this margin of profit the tendency on the Pacific coast, where the business is conducted on a gold basis, is to force the trade dollar into circulation, and being at a discount as against gold, inconvenience in retail transactions is experienced. Moreover, it conflicts with the sound principle that wherever an overvalued coin circulates as money, by reason of its legal tender power, the seigniorage or difference between its bullion and nominal value should be realized by the Government and not by individuals.

"Under existing laws deposits for trade dollars may be made without limit, the depositor paying the expense of coinage, while all other silver coins are fabricated exclusively on government account.

"The purpose for which the trade dollar was authorized would not be interfered with if the provision of law making it a legal tender should be repealed, and it is believed that such repeal would prevent any complication in future with our monetary system, as the coin would not differ in any respect from a stamped bar, except in being of uniform weight and fineness, and of form for convenient use.

"If a silver dollar should be deemed necessary as a coin of circulation, it should be made of the same standard as the present silver coins of less denomination, and coined and issued exclusively on government account. There can be no objection to the issue of such a coin. On the contrary, it would be productive of some advantages.

"I inclose for your consideration a draft of a bill which, if enacted into a law, will confine the trade dollar to the purposes originally intended, and give a dollar of circulation of the same standard as the present half and quarter-dollar, twenty cent piece and dime, and a legal tender to the amount of ten dollars.

H. R. LINDERMANN."

Yield of the Comstock Mines.

Following is a statement of the proceeds of the mines of Storey county, Nevada, for the quarter ending December 31st, 1875, from the quarterly assessment roll:

BELCHER—Tons extracted, 30,268; value per ton, \$32; gross yield, \$969,762.51; total cost of extraction and reduction, \$600,104.27; net yield or value upon which taxes are levied, \$369,658.24; total amount of tax, \$4,998.81.

CHOLLAS-POTOSI—6,750 tons; value, \$16; yield, 110,890.64; cost, \$164,976.18; net yield, \$22,178.13; tax, \$277.23.

HALE & NORCROSS—2,950 tons; value, \$17; gross yield, \$32,720; cost, \$79,782.87; net yield, \$10,310.84; tax, \$128.89.

IMPERIAL—2,727 tons; value, \$27; gross yield, \$74,005.55; cost, \$55,923.01; net yield, \$18,083.54; tax, \$226.04.

CROWN POINT—29,742 tons; value, \$17; yield, \$506,010.79; cost, \$600,724.31; net yield, \$101,202.16; tax, \$1,265.03.

CON. VIRGINIA—26,792 tons; value, \$119; yield, \$3,205,906.92; cost, \$1,653,699.16; net yield, \$1,602,953.46; tax, \$20,036.92.

EMPIRE—2,560 tons; value, \$12; gross yield, \$32,720; cost, \$20,480; net yield, \$12,240; tax, \$153.

JUSTICE—7,297 tons; value, \$23; gross yield, \$16,865.78; cost, \$12,784.25; net yield, \$4,081.53; tax, \$52.02.

OPHIR—9,169 tons; value, \$45; gross yield, \$419,264.98; cost, \$208,734.50; net yield, \$217,530.48; tax, \$2,719.13.

VIVIAN—1,488 tons; value, \$15; gross yield, \$23,397; cost, \$20,561; net yield, \$4,679.40; tax, \$58.49.

YELLOW JACKET—761 tons; value, \$16; gross yield, \$12,176; cost, \$13,698; net yield, \$2,435; tax, \$30.44.

EXPRESS MILL (tailings)—1,800 tons; value, \$9; gross yield, \$17,100; cost, \$16,200; net yield, \$1,710; tax, \$21.38.

RAILROAD MILL (tailings)—4,000 tons; value, \$11; gross yield, \$44,000; cost, \$35,743.25; net yield, \$8,256.75; tax, \$103.59.

Idaho Mines.

A correspondent of the *Owyhee Avalanche*, writing from Heath district, says:

I see by the returns of the bullion shipments from the different States and Territories that Idaho has the past year instead of increasing her product decidedly reversed the case. Now, it is not for the sake of writing a glowing account of Idaho's prosperity that I will endeavor to show the cause of such an apparently anomalous state of affairs, to wit: That a young and progressive Territory should not increase her staple product, i. e., the bullion yield; the cause is such that, instead of being a sign of decadence, it is quite the contrary and must naturally redound to the future and permanent welfare of our country.

One of the most important causes is that for two years past the yield of gold in Boise Basin—the principal placer mining district of the Territory—has diminished purely through natural causes and that simply on account of the absence of water through the insufficiency of snow in the early part of the mining season; either there was no water, as was the case in 1874, or, as in 1875, the water went off with a rush too early to be of use to the miners.

Another and most important item is that the immense amount of gold yielded by some of our mining corporations was stopped on account of work being suspended in the upper levels, while they were placing their mines on a basis by the erection of hoisting works, sinking shafts and other necessary improvements for the better and more permanent success than ever heretofore attended them. This case may be illustrated by the works of the Gold Hill mining company, at Quartzburg, where over \$40,000 has been expended and not a return of a single dollar the whole year. The energy and perseverance of this company cannot be too highly extolled. It looks well for the ledges around the basin that a company like this could keep their 25-stamp mill running day and night for six months steady and then slap out to the tune \$40,000 to work below water level. They have their reward, for the ledge recently struck at a depth of nearly 200 feet has proved what all mining experts coincide in, viz.: That in the quartz the richest ore will always be found below the water level of the district.

Another item on the improvement of the country, which has kept thousands of dollars at home, has been the erection in the Banner district of a 20-stamp mill by Mr. Crafts of Idaho City. The ledge to be worked by this mill is among the richest yet discovered in any country, and when worked, as it will be the forthcoming season, will augment the yield of bullion to an extent that will hardly be deemed credible for an Idaho mine; and it will be no desultory hit or miss affair, for the mine has been thoroughly opened and prospected and the mill fitted with all the requisite appliances for saving the metal, and everything is in order for the word "go."

Instances could be mentioned *ad infinitum*, if necessary, to show that circumstances over which we had no control, such as the Bank of California, and other affairs, all helped to cause the recent retrogression. Idaho is to-day on a firmer and more prosperous basis than ever before. It is true, people growl, but then they do not know what it is for, except that they must be in fashion. The fact is, we are too well off—a good living is too easily obtained if anything. If some of our soreheads would go back East, where men are crying and rioting for bread alone, they would return better contented, I fancy; or even let them take a trip to "glorious California" and rattle, and my word for it, their first song would be, "Oh, carry me home."

The situation is easily accounted for: The mining extravagance of a bygone day has left its traces behind. Used as many have been in our palmy days to having money in plenty and scattering it as fast as we made it, it rather goes against the grain to have to look after picaunies; yet, as Shakespeare says, "to such a complexion must we come at last." So, the sooner we all quit growling, look upon the sunny side of life, live for the present instead of the future, and above all, put our shoulders to the wheel, and do the best for ourselves, the sooner our troubles will be over and we shall be better off.

Idaho is no exception to the general rule applying to all mining countries. In California and Colorado, after the cream, as it were, had been taken off, there was an era of decadence, we heard the same cries of the wounded, "a God-forsaken country," "the country's gone in," and many other choice epithets; well, if we look at either country to-day, we can see that the poor miserable wretches did not hurt it much. This class as a rule are of no account to themselves or anybody around them. Another thing in regard to Idaho's great failure and I am done: As a parallel to our Territory I will place what was once known on the maps as the Great American desert, embracing Kansas, Nebraska, Colorado, etc. Before being known it was supposed to be the home of the buffalo, there "the deer roamed and the coyote loved to dwell," and it was honestly supposed that the whole country was unfit for human habitation; now we see them among the highest stars in the galaxy of States, and just so sure as this then apparently worthless country has by progression and enterprise been transformed into a blooming garden, just so sure, and in our time, too, will Idaho march with giant strides to the front. Our now tenantless valleys will blossom as the rose, the sage brush

plains will be verdant with grain and our mines will be worked for their value—with the new improvements for saving the precious metal, who can even imagine the wealth our mountains will annually produce?

Right here in this district we have ledges of iron, copper, galena, silver and gold, all the base containing a good paying percentage of gold and silver; but we want men with money and brains to assist in the development of the whole country, and until we get them, and not until then, will Idaho be worthy of her appellation, "the gem of the mountains."

Nevada County and its Prospects.

A recent number of the *Nevada Transcript* says:

The county of Nevada is in size about the same as the State of Rhode Island, having an area of nearly 1,200 square miles. Its surface is generally mountainous or hilly, with occasional fertile valleys between. The soil is of a reddish color, and it is mostly side hill or table land. With irrigation, a great portion of it will produce almost any kind of crops. There is at present, however, but a mere tithe of the land cultivated. Last year it was estimated that only 16,000 acres were used for agricultural purposes. Doubtless when the railroad is completed a greater area will be cultivated.

Agriculture.

As fine potatoes as can be grown in the State were raised here the past season. There are thousands of acres of land adapted to their cultivation, which is conveniently located for irrigation, yet there were only 3,000 tons raised in all the county last year. Much of the soil is also adapted to the production of wheat, barley and hay, even without irrigation, yet there was not half enough produced to supply the home demand, and the balance had to be furnished by ranchers from near the valleys. The county only produced last year about 3,000 tons of hay from about the same number of acres. One-half the same area sown to alfalfa would produce double the amount if convenient to irrigation. The soil and climate are well adapted to

Fruit Growing.

And the fruit is acknowledged to be superior to that grown in the valleys, yet in all the county there are only a little over 400,000 trees and vines of every kind. In all the lower and middle portions of the county trees grow luxuriantly and produce bountifully with but very little care and cultivation. Fruit growing can be made an important industry, and one that will prove remunerative as soon as means to ship to market are furnished. Nut bearing trees seem almost indigenous to the soil. They grow rapidly and bear liberally, but there are as yet few planted. There are in the neighborhood of 1,200 miles of mining and irrigating ditches, along the line of which are opportunities of irrigating ten times the soil now under cultivation without materially interfering with the supply necessary for mining.

The Population of the County

Is something less than 20,000, and its assessed value of property is less than \$9,000,000. Quartz mining is the leading interest in the southeastern part of the county, yet there are but 43 mills in operation in the county. There are ledges in every direction, yet unworked, however, and it is expected the new process of Fryer will in a few years enable four times the present number worked to be properly developed. The whole upper portion of the county is clothed with pine, spruce, fir and other trees adapted to the manufacture of lumber, yet there are only 27 saw mills in operation, and only 50,000,000 feet of lumber sawed and 25,000,000 shingles made annually. There are over 100 miles of ancient river channel which are

Rich With Precious Metals

Within the borders of this county, yet there are probably less than ten of them even commenced to be worked. From the above facts we feel justified in saying that the natural resources of the county are not excelled by any similar one in the State; and but comparatively little has yet been done to develop them; that the field for enterprise here presented is superior to any section, and that in the near future, when it becomes known, capitalists and men of small means will avail themselves of the splendid opening awaiting their investment. The county is capable of supporting tenfold its present population. The prospect at present is certainly very flattering for the unparalleled prosperity of this section, and we see nothing to prevent the county from becoming second in importance in wealth and population only to but very few in the State.

A HORSELESS WORLD.—A Western paper amuses itself in this way: What a queer world it would be! No dry horse or cart horse in the streets; no race horse sweeping over the track; no cavalry horse on the battle-field; no lady's palfrey proudly prancing; no mustang on the plains; no Shetland pony; no Canadian sleigh horse; no canal boat horse nor artillery horse; no stallion in Kentucky; no horse for Sheridan to ride, or Grant to drive or Mazepa to fly with. A horseless world wouldn't be the world to which we have been accustomed. We should miss the kindly face of the animal which has been called the "friend of man;" which has served him so faithfully; which has performed the hardest work for him; which has helped him to fight his battles; which has done so much to render life enjoyable, and which has been so cruelly created by the hard-hearted.

MECHANICAL PROGRESS.

Vegetable Fiber for Plastering.

Notwithstanding it is well known that the animal hair used in mortar for plastering ceilings is soon destroyed by the caustic action of the quicklime, its use for keeping plaster together has been persisted in from time immemorial. This is so much more surprising, as it is well known by all who handle acids and alkalis, that the latter act in an opposite way from the former on vegetable and animal fibers; while mineral acids, like oil of vitriol, etc., do not attack animal substances like hair, the mineral alkalies, as potash, soda, lime, etc., do so; but on the other hand, they do not attack vegetable fibers, which are as safe against caustic alkalies as animal fibers are against acid. Therefore quicklime acts on hair in a similar way, and more so in proportion as it is more caustic; of course the hair used soon becomes rotten, and very often does not prevent the plaster from falling off, as is well known by those in the business.

At last the idea was conceived of substituting a vegetable fiber for the hair, which was so successful that the invention was patented, and after experimenting with various kinds of vegetable fibers, it is now prepared and furnished to builders, masons, plasterers, architects, and contractors.

Every one knows that the animal hair, as sold to the trade, is very impure, containing some 30 per cent. of its weight of impurities, as lime and scrapings of hides, while the hair itself, by the caustic action of the quicklime used in the process of removing it from the hides, has been greatly damaged and lost some 50 per cent. of its original strength. The objections to the hair thus far used are: 1st. It is more than half rotten by quicklime when bought. 2d. It can not resist the action of the lime in the plaster, but soon rots entirely away. 3d. It contains at least 30 per cent. of dirt and dust. 4th. Besides this loss in quantity, there is much short hair which is of no use in the plaster.

This new material is sold in New York city, under the name of the patent vegetable plastering fiber. The advantages claimed for it are: 1st. Being of a woody nature, instead of being destroyed when put in the lime, it is preserved—lime being a preserver of wood. 2d. It is light and bulky, so that one pound, costing only 20 cents, is sufficient for a barrel of brown, and two pounds for a barrel of lime scratch coat. 3d. It is much stronger than hair, is very light, clean, and perfectly free from dirt. 4th. It mixes more easily and freely with the plaster than is the case with hair, and also spreads much more evenly through the same. This substance is packed in bales of two pounds each, ready for use, and has only to be whipped a little to lighten it up, and scattered over the lime, which should be first thoroughly slacked.

Application of Solar Heat to Industrial Uses.

A Mr. Monchot has just invented a machine composed of three principal parts, to-wit: a metallic mirror with a linear focus, a blackened boiler whose axis coincides with this focus, and a casing of glass permitting the solar rays to come to the boiler but opposing their egress until they have been transformed into obscure rays by the latter. The opening of the mirror, which is in the form of a truncated cone, is turned toward the sun. The sides of the cone make an angle of 45° with its axis. The bottom of the mirror is composed of a disc of cast iron, which has for its object the diminution of the force of the wind.

The boiler, which is of the same height as the mirror, rises from the center of the disc, and is of copper, blackened on the outside. It is composed of a double casing, between the inner and outer of which is the feed water.

The following is one of the results obtained with this apparatus under ordinary circumstances, to-wit: 20 liters (1,220 1/2 inches) of water were introduced at 20° (68° Fahrenheit); in 40 minutes they produced steam of two atmospheres, and a few minutes later of five atmospheres. The steam served for the working of several motors.—*American Manufacturer.*

PLATING COPPER AND BRASS.—Copper or brass, says Armand Bertrand, may be plated with bismuth in a bath composed of 25 or 30 grammes of ammoniacal chloride of bismuth per liter of water, slightly acidulated with hydro-chloric acid, operated cold. If heated to 100 degs. the bismuth will not deposit. A single Bunsen cell only is necessary; with a single Daniel cell the deposit is long forming and but slight. On coming from the bath, the articles are covered with a dark deposit, under which is the bismuth with its especial brilliancy, and adhering strongly. By substituting the double chloride of antimony and ammonium, antimony may be similarly deposited.

A NOVEL MODE OF WELL BORING.—In various parts of Scandinavia the boring of artesian wells is done by means of a jet of water. The stones in the diluvial ground, which are a great hindrance to such operations, are thrust one side by the jet, if small; while if large they are shattered by dynamite. In Kiel 22 artesian wells have been bored within the past six or seven months.

Combined Steel and Iron.

In addition to the advantages alluded to last week as derivable from Wheeler's new mode of welding steel to iron, we may mention, as of great importance, its application to the manufacture of fire arms—both small arms and cannon of the largest caliber. Mr. Wheeler holds that the past manner of casting cannon, in not excluding the atmosphere from the mold while molten metal is being poured in, accounts for the brittleness of the gun metal in general, and its lack of resisting force to a great expansive power.

Hitherto the great problem has been to discover a gun that would be light and economical and at the same time capable of great endurance. The best known cannon now in use is the Armstrong gun in England. This inventor, after spending hundreds of thousands of pounds for the government, brought out a gun that secured him a knighthood. The Armstrong gun is of iron entirely. The great trouble with an iron gun, however, lies in the fact that it is subject to abrasion from the friction of its load, so that in time it becomes very inaccurate from irregularities produced upon the surface of its interior. A steel surface is necessary to guard against this abrasion, but a gun made entirely of steel has no resisting strength, as compared with an iron gun. The famous Krupp gun of Germany is a steel gun, but it sometimes bursts after a second discharge, as was the case with the last experiment made with a gun of extraordinary caliber. For years the great problem has been to combine steel with iron so that a gun might be found that will have a steel lining for its interior, to prevent abrasion, and iron exterior to secure the desired strength. Steel is also much more expensive and heavy than iron, so that an iron gun with steel lining would of necessity be lighter, more economical and effective than could any of the guns made of steel alone. It would also have a strength far superior to the best Armstrong gun. To solve this problem has required the welding of steel and iron in such a manner that a homogeneous mass would be produced, combining the desiderata of good qualities. Hence Mr. Wheeler's combined iron and steel plan has been called the Armstrong married to the Krupp. It is the successful solution of a problem upon which the warlike nations of the world have expended millions without, heretofore, any very satisfactory result.

In regard to small arms it is said that Remington, Sharp, and Mrs. Colt have made overtures to use the process in the manufacture of their weapons. It is claimed that the invention, so long sought after, is but another discovery of the identical process used in the manufacture of the celebrated Damascus blade. Certain it is that all the leading naval officers, from Admiral Porter down, are very enthusiastic upon the subject of this improvement.

THE CONSTRUCTION OF REVOLVING DRAWBRIDGES.—Mr. Clemens Herschel has presented to the American Society of Civil Engineers a paper on the principles of the construction and calculation of the strains in revolving drawbridges, and his work has an important value as one of practical interest to the profession of engineers. The calculation of continuous girders was first undertaken by Navier in 1830, but was much improved upon by Clapeyron in 1857. These and other authors have, however, Mr. Herschel states, developed only special cases, and he has undertaken to develop the equations for the general case of unequal spans and supports, either in or out of level. Following the equations given in a recent work of Weyrauch, Mr. Herschel gives in detail the formula necessary to compute the dimensions of every part of the bridge in question, and illustrates the whole by numerical examples. The several equations are written out in full, and are so clear as to enable any one to follow the processes with ease. A couple of tables, showing the strains experienced by every portion of a bridge under certain loads, gives a very lucid view of the relative strength demanded in the various portions of the structure.—*Iron Age.*

LOSS OF POWER IN THE STEAM ENGINE.—The following table, from an article by Messrs. Hunt and Skeel, on "The Methods of Testing Steam Engines," gives a good idea of the quality and amount of the losses, in the case of a condensing engine connected to a propeller:—

Units of heat in 100 lbs. anthracite.....	1,400,000	
Heat equivalent to weight of ashes.....	200,000	
Total heat in 100 lbs of anthracite.....	1,200,000	100
Carried off by hot gases in chimney.....	200,000	16 2/3
Available to produce steam.....	1,000,000	83 1/3
Lost by leakage and condensation.....	200,000	16 2/3
Available for work in cylinder.....	800,000	66 2/3
Escaped with steam into condenser.....	600,000	50
Transformed into work.....	140,000	11 2/3
Absorbed by friction, etc., of engine.....	40,000	3 1/3
Available for useful work.....	100,000	8 1/3
Absorbed by friction, etc., of propeller.....	20,000	1 2/3
Usefully applied to propulsion.....	80,000	6 2/3

FIRE-PROOF JOIST.—An ingenious kind of fire-proof joist, recently introduced, consists of a slip of wood five inches wide by five-eighths of an inch thick, belted between two flanged strips of quarter-inch iron, making a beam quite as strong as those of wood ordinarily employed. The iron sides, in addition to affording strength, it is claimed, render the joist substantially fire-proof, while the center of wood affords the means of putting down floors and nailing on laths in the usual manner. The impediment to the manufacture of these joists heretofore has been the difficulty of rolling the flanged iron sides, but this has now been successfully overcome.

SCIENTIFIC PROGRESS.

Chemistry in its Relation to Modern Thought.

The above was the title of a paper read by Mr. H. B. Baildon before a meeting of the North British branch of the Pharmaceutical Society, held in Edinburgh recently. In the course of his remarks the reader showed that to chemistry was entrusted the task of tracking matter back to its simplest form or forms, and the result, so far as present knowledge went, was remarkable. There were over 60 elements which had hitherto defied all attempts to resolve them into a further simplicity, and these were indestructible, passing seamless and invulnerable through every transformation. While of course it was open to the theorists to hold that these elements were varieties of some ultimate single substance, there seemed no prospect that a proof would ever offer itself. No doubt the fact that all the elements had different atomic weights, and that in some cases we found elements which bore a family likeness, forming a series in regard to their atomic weights—affording, as it were, a glimpse of the wondrous staircase of creation; yet as there appeared to be no means of further analysis, this theory seemed fated to remain a theory. Like all sciences, chemistry was full of unanswered questions. Mature and elaborate as it was, it had not surrendered the keys of its causation. We might talk glibly enough of chemical affinities though we could give no reason for them. It was possible that at some future time a further step might be made; some relation between the form of the molecules and these affinities might be discovered. But it seemed certain, from all previous experience, that, virtually, the same question would remain unanswered—a law being found according to which the molecules attract each other, but for whose existence no reason could be assigned. Passing on to inquire what bearing chemistry had upon Mr. Tyndall's notion of matter, the professor found in matter, firstly, the "promise of all terrestrial life." Did that mean there was nothing but matter in existence? If so, it was contradictory to the professor's own admission of the mystery of mind. Did it mean that the material or physical universe consisted of matter? That was tautologic. Or did it mean that matter traced back to its simplest forms gave promise of its future destiny? If so, this last could flatly be denied. Matter in its simplest forms consisted of a number of separate elements. So long as these were kept apart, they exhibited peculiar and distinct properties. But take two whose single properties were known, and allow them to combine, when there appeared what was virtually a new creation—a substance possessing qualities different from those of its constituents. Neither of these, therefore, could he said to afford the promise of the resulting product. After a reference to the law of combination by weight, the reader treated of a combination by volume, diffusion of gases and crystallization. He concluded by saying that to his mind the fact of crystallization was higher than that of any law they had yet dealt with; it declared most distinctly the connection between beauty and purity, the tendency of the crystal being to cast out all chemical impurity.—*Iron.*

THE scientific report of the Austro-Hungarian Arctic expedition represents the effect of extreme cold upon the human body in high northern latitudes as usually much exaggerated. Among the sailors there were some who did not wear fur coats at all, and even in the coldest weather they smoked their cigars outdoors. It is only when accompanied by wind that the cold produces serious discomfort; but the violent winds common in southern climates are unknown near Francis Joseph's Land, the northernmost country yet discovered on the earth. The belief that the polar ice tends strongly to calm the winds is commonly entertained by Arctic sailors. Among the more remarkable discoveries made by Lieutenant Weyprecht is a curious fact about the drift of Arctic ice; it does not drift straight before the wind, but invariably deviates to the right, looked at from the center of the compass. The deviation cannot be accounted for, either by the conformation of the neighboring coasts, or the existence of currents which might produce it, as it occurs with winds blowing from opposite directions.

FORMATION OF SUGAR IN BEETS.—The discussion on the subject of the formation of sugar in beets continues to be warm, but is very far from having a satisfactory conclusion. The great authority, Claude Bernard, is of opinion the sugar is formed by the root. Messrs. Duchartre and Viollette believe it takes its place by the leaves, owing to the conversion of the starch in the leaves into saccharine matter, the root being merely the depot for the sugar thus formed, to nourish the seed stem the following year, just as the tubercle of the potato has a store of starch to feed its shoots of the succeeding season.

ORGANIC ELEMENTS AS ELECTRO-MOTORS.—It appears, from the author's researches, that the interior of a muscle is negative, which indicates that there is oxidation in the interior and reduction at the exterior, and that all organized bodies appear formed of—so to say—an infinite number of electro-motors, which intervene probably in the phenomena of nutrition.—*Becquerel.*

Formation of Ultramarine During the Incineration of Bread.

I do not find any note of the fact that, at a certain stage in the incineration (burning) of bread, the beautiful ultramarine blue is formed. This occurs under circumstances which I have not yet sufficiently studied to enable me to reproduce it with certainty; but if the heat be raised to very bright redness, or be prolonged after complete incineration of the bread, the blue passes into a beautiful turquoise color, then becomes green, then passes on into a rusty color, and finally comes out as a pale fawn-colored lining to the botryoidal mass of ash. This is not further affected, even by a prolonged white heat. The tints are so suggestive of the presence of copper that only by very careful examination did I satisfy myself of the absence of that metal; and I find that the colors occur in the purest and finest bread, as well as in inferior samples. I should be grateful if other analysts would favor me with any observations which they may have made upon this point, and I hope soon to be in a position to submit for myself some further account.

It is curious that copper should appear in all the text books as one of the agents ordinarily used for adulterating bread, and the question arises whether the supposed use of copper may not sometimes have been erroneously inferred from the occurrence in bread ash of these beautiful colors.—*James Edmunds, in Chemical News.*

GEOLOGY AND THE BLAST FURNACE.—Geologists have given us as a theory for the creation of columnar formed trap rock that it is of igneous origin. Prof. James D. Dana says: "While stratification has come from the successive formation of beds these columns are a result of the cooling. Cooling causes contraction of the solid rock, and as cooling went on produced the fractures. These fractures are always at right angles, or nearly so, to the cooling surfaces. Where the rock fills the vertical fissures the columns are horizontal. Even sandstones have been rendered columnar where overlaid by beds of trap, or when they have been subjected otherwise to heat." Electricity and motion have also been given as causes of the columnar forms of rock, but as another evidence of the correctness of the former theory it is stated now, although it has been long known to blast furnacemen, that "the sandstone bottoms of iron furnaces assume, from the long continued action of heat, a distinctly columnar form, the old lines of stratification being obliterated, thus showing that heat, as well as electricity and mechanical force, was an agent in the production of the columnar form of rocks." And thus work of man is quoted to illustrate and prove the workings of nature.—*American Manufacturer.*

NO REST.—Science teaches us that the crust of our earth is perpetually moving, and that the sea level is constantly changing. Our globe has its daily rotation on its axis and its yearly revolution about the sun. The sun, with all its satellites, sweeps on toward a moving point in the constellation Hercules. Every so-called fixed star is in motion. Fifty thousand years ago the constellation of the Great Bear or Dipper was a starry cross; a hundred thousand years hence the imaginary Dipper will be upside down, and the stars which form the bowl and handle will have changed places. The misty nebulae are moving, and besides are whirling around in great spirals, some one way, some another. Every molecule or matter in the whole universe is swinging to and fro; every particle of ether which fills space is in jelly-like vibration. Light is one kind of motion, heat another, electricity another, magnetism another, sound another. Every human sense is the result of motion; every perception, every thought is but motion of the molecules of the brain translated by that incomprehensible thing we call "mind." The processes of growth, of existence, of decay, whether in worlds or in the minutest organisms, are but motion.—*Scientific American.*

SCIENCE IN THE PUBLIC SCHOOLS.—At the close of his series of six Christmas lectures, in London, on electricity, Prof. Tyndall remarked that five of them had been illustrated with apparatus which any teacher could make of the commonest material, at scarcely any cost. He hoped the example thus set would be followed, for the future of science depended to some extent on teachers in the public schools. The masters of schools, he said, should look the problem of scientific education straight in the face, for science was growing day by day and hour by hour, and although he would deprecate any change from without in the public school system, he would advise the masters to make the change from within, before the outside pressure became too strong.

PURIFYING COPPER.—A process has been patented by Mr. S. L. Crocker, of Taunton, Mass., which consists in adding zinc in small quantity in a furnace to the copper ore or ores, or to the partially refined metallic copper therein, containing arsenic and antimony, whereby, it is claimed, those impurities can be readily removed.

CONSOLIDATING ASHES.—The discovery of a process by which ashes can be converted into a solid mass as hard as marble has revived the discussion of cremation in Germany.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

WILDA MINE.—*Amador Ledger*, Feb. 19: The supply of wood is about exhausted at this mine, and the work of taking out rock has been suspended in consequence. Most of the miners have been temporarily discharged. The principal work at present carried on is the hauling of water. The roads are in such a condition that wood cannot be obtained to keep the mine in full operation.

BARROW MINE.—This mine, situated near Drytown, has been idle for years. We now hear that Hayward has bought a large interest in it, and that it will shortly be started up. The recent splendid developments in the Gover mine, in the same locality, has drawn attention to this abandoned claim, and there is every probability that it will be put in working order in the spring.

CONGREGATED.—The mill of the Amador Consolidated mine was started up on Saturday, for the first time since the fire. They are running 20 stamps, on rock from the old Badger-shaft. The tunnel is almost through. In crossing the middle shaft it was found to be filled up with earth, timbers and mining debris of all sorts. The prospects of the mine are decidedly bright.

NECROT.—David Brown, the other day, picked up a handsome nugget of gold and quartz on Sutter creek, about two miles above the town. It is worth \$9.

NEW QUARTZ LEDGE.—Messrs. McIntyre, Burleson and Hayden, of Sutter Creek, have commenced prospecting on what appears to be a new ledge, a short distance west of the Amador Consolidated mine.

The ledge is a vein of quartz, and is covered 12 feet thick, showing sulphurets and some free gold.

NEW CLAIM.—Holmer Turner, Charles Stecker and others, this week took up a placer claim situated about half a mile north of the quartz claim located by them last week.

SHARP & BOXALL CLAIM.—Two miles of flume has recently been constructed to supply this claim with water from the Butte ditch. The hydraulic operations are much retarded by the caving of the ground.

THE BONANZA CLEAN UP.—The clean up at the Bonanza mine of Drytown turned out well, realizing \$1,800, an average of \$5 per ton. They will clean up again at the end of the month. This may now be regarded as one of the paying mines of the country.

BUTTE.

SALE OF DITCH PROPERTY.—*Butte Record*, Feb. 19: The West ditch, which takes water from Butte creek, near the site of the old Neal saw mill, and conveys it to Thompson's flat, has recently been sold to C. B. Powers, F. B. Miller and J. T. South. In connection with the ditch were some 1,400 acres of land, lying along the north bank of Feather river, opposite Oroville, and being part of the Fernandez grant, sold in connection with the ditch. The sum paid for the property is said to be \$45,000. It is possible that a portion of this ground may prove moderate mining ground, but we should judge the whole thing was put up to sell in a desperate manner.

The original corporators and fell into the hands of their hired superintendent. The Fernandez grant was a floating swindle that was located partially on mining ground, and confirmed by government through the influence of a former U. S. District Attorney, to himself and others. The ground has been mined for years and never made as successful a clean up as the present reported sale. We supposed it is to be rendered profitable as was the Emma mine, by working it off in England.

CALAVERAS.

NUOGET.—*Calaveras Chronicle*, Feb. 19: A nugget of gold was picked up on Marietta street on Friday of last week by Mr. Charles Page. This place, the streets of Mokelumne Hill resemble those of New Jerusalem in more respects than one.

CONTRA COSTA.

EMPIRE COAL MINE.—*Antioch Ledger*, Feb. 19: The proprietors of this valuable mine, Messrs. Rouse & Harburt, are pushing ahead preparatory to shipping coal as soon as the roads are passable for heavy freight. The main shaft is now down 525 feet, and the force of men employed, 30 in number, are running gangways and air shafts. The coal is of excellent quality, and the vein perhaps the largest that has been discovered on the coast. Work has already commenced on the new county road leading to the mine, and it is believed a railroad will also be completed from the mine to Antioch during the summer.

INYO.

DARWIN DISTRICT.—*Coso Mining News*, Feb. 17: In the Delance mine work in all the drifts and levees as mentioned in our last issue, is being vigorously prosecuted, and at all points we have inspected the mine is constantly improving to a wonderful degree, particularly in the drift being run from the bottom of the south winze, which is the deepest working on the mine, being about 110 feet below the croppings.

DEFANCE FURNACE.—The furnace has been running very successfully for the past 10 days, and is fast to make an extended run, as everything is in fine working order. The weather being warm and pleasant the snow in the mountains is fast disappearing and very little more trouble is apprehended as to a further and sufficient supply of coal. During the nine days actual running time 974 bars of bullion have been made, 874 which have been shipped. There were on hand last night 100 bars. The bullion is gradually increasing in richness of silver.

CUERVO FURNACE.—The Cuervo furnace has not been running during the past week for the reason, we are informed, that no coal is obtainable just yet.

NEW COSO FURNACE.—The furnace is running very well indeed, and turning out large quantities of high grade bullion.

GOLD DISTRICT.—Some two miles south of Lookout is a gold district, the formation being granite, while that at Lookout is limestone. There are numerous locations made here of gold-bearing mines, and many of them are of much value. Specimens can be obtained which will assay all the way from \$40 to \$40,000 per ton. The lodes vary in width, ranging from a few feet to 100 feet. The croppings are traceable for long distances, and being in a granite formation, accompanied with porphyry dikes, there is hardly a doubt but that the ledge will go down to a great depth. Water is close at hand for steam purposes, and wood within three miles; and all that this portion of Lookout district needs to make it the peer of any in Inyo county, is capital for the development of the mines and reduction of the ores.

HEMLOCK (PANAMINT).—From Judge J. M. Murphy, who called at our office the latter part of last week, we learn that a big strike has been made in the Hemlock mine, at a depth of nearly 500 feet, a solid body of pure black metal having been discovered which is three feet in width, the ore averaging \$400 per ton. Considerable excitement was caused in the camp in consequence of the strike.

LEE DISTRICT.—Geo. M. Frink, son of J. B. Frink, came in from Lee district yesterday and informs us that the timber frame for the Emigrant company's mill is all on the ground awaiting the arrival of the machinery, which has been lying at Caliente for the past month.

MONO.

BENTON.—*Cor. Inyo Independent*, Feb. 12: Both mills

are shut down at the present. Mr. Mack's mill has not been running for some time for the want of ore, as erecting the hoisting works and laying new track prevented getting ore to the surface. The Diana mill has been undergoing a thorough repairing under the supervision of Mr. Julius Partz, and will start up to-morrow, and as the mines are looking well, the mills ready to start and as the weather coming, we may expect to see a few "Benton bits" in circulation. Messrs. Thompson & Triman have about completed their astrata at Moore's creek, when they expect to be able to run three tons of ore in 24 hours, and as their ore is quite rich and free from base metals we do not see anything to prevent them from realizing a handsome profit on the venture. Mr. Partz, a Montgomery canon, has lately struck a vein of ore about one foot thick and said to assay in the thousands, but we do know if Mr. Kays has very much ore of the specimen he exhibited here a few days ago, he is fixed for the Centennial.

NEVADA.

PROSPECTING.—*Nevada Transcript*, Feb. 19: There is considerable prospecting going on in the county, but a large number who claim ledges are waiting for further developments of the Fryer process. They have claims on ledges which they can hold, and do not choose to do more work until they are perfectly satisfied that rock can be more cheaply reduced than by the present methods.

NEW LEDGES.—Three miners commenced some time since to prospect a ledge located near the corner of the old Nick Turner lot, beyond Plety hill, and are now drawing the rock to Kitts' mill to be crushed. They have sunk 40 feet on the ledge, and then drifted far enough to get out a ton of rock, which will now be crushed. The rock shows considerable free gold. The ledge is in the neighborhood of a foot in width, and it is thought will be proven by the crushing to be valuable.

BAY'S RANCH MINE.—*Foothill Tidings*, Feb. 19: The Bay's Ranch mine is now being developed for the purpose of finding what the ore will do by the Fryer process. The description of the rock, which will now be paid well, but the rock below the water line was more refractory and failed to pay by common mill treatment. The new method of working is bound to bring out many a mine now considered worthless.

The Franklin, Allison Ranch, mine is looking up in the estimation of the public, and the owners are about to erect steam works thereon and thoroughly open it up. It is thought to prove equal to the old Allison Ranch, as its friends claim it may, that region will once more be alive with busy miners.

The prospect is that the Prospect company have a fine mine in the old Perseverance, down below Allison Ranch. Stock in this company which went begging for buyers at the value of the assessments which had been levied thereon, only a short time since, is snapped up now around \$100 per share.

OSAHIA.—A new water wheel is being built at this mine to cheapen and facilitate the work on mine and mill, and the general outlook for this company is good. Big clean-ups are getting to be the regular thing at the Omaha.

EMPIRE MINE.—Late developments in this mine are the most encouraging nature. The Empire is now working the best in the county. They are now working a large force and splendid returns may soon be looked for. It is thought to be a No. 1 mine.

PLACER.

A FINE NUOGET.—*Placer Argus*, Feb. 19: We saw a nugget yesterday at Andrews & Hollenbeck's bank that was enough to recall the olden time when gold was plenty in the ravines around Auburn. It was the property of Juan Romero, who found it while mining in Baltimore ravine. It was of irregular shape, almost as large as a man's fist, and weighed 23 ounces and 15 pennyweights. It proved equal to the old Allison Ranch, as its friends claim it may, that region will once more be alive with busy miners.

SAN BERNARDINO.

Los Angeles Land Journal, Feb. 15: There is a prospect of the early resumption of operations in the Temescal tin mines in San Bernardino county. These mines are situated on the south side of the San Bernardino settlement known as Pomona. During the past 10 years but little labor has been performed in these mines on account of a conflict in regard to the title. The property is reputed to be immensely valuable, and it is unfortunate that an industry of so much importance should languish on account of a wrangle over the right of possession. But it appears that the conflicting interests will soon be smoothly adjusted, and that a company of foreign capitalists will vigorously take hold of the work. The prospective operators are wealthy gentlemen from Amsterdam, who are engaged in importing tin from the United States on an extensive scale. The value of tin annually imported by them is given at \$14,000,000. It is stated that they have secured a large tract of land, and that the money will be paid on the 1st of May next, and it is believed that the resumption of mining operations will greatly benefit business and property interests in that section.

SISKIYOU.

SALIVATON.—*Yreka Journal*, Feb. 19: The quicksilver mining company in Trinity valley has shut down on working any more cinabar this winter, being unable to procure hands, as several have been salivated, owing to the mortar used in the brick retorts, having been made from the tailings of the cinabar. The furnaces have been shut down, and the mortar will be replaced, and then the cinabar tailings, in order to get the men to work the retorts. The contracts for lime and other supplies from Scott valley, however, continue the same and will be fulfilled as contracted. When new retorts are built, the work of retorting will go on again with still greater success.

MINERS.—On Patterson creek, in Scott valley, more ground sluicing and hydraulic mining has been done than during any winter since the claims have been taken up, and work will be continued, undoubtedly, all summer, which is an unusual occurrence on that creek. A large amount of gold will be taken out this season, which will make times lively and prosperous in the neighborhood. On Cherry creek and Deadwood, the miners are busy with a better supply of water than for many years, and plenty of snow on the hills to keep it up until late in the summer. At Indian creek and Oro Fino, the cold weather stopped the supply by freezing, but as the weather is warm again, there will be an abundance to permit successful hydraulic mining, ground sluicing and other methods. The miners are busy with a better supply of water, and are working every day, Sundays included, and some of them nights also, when the weather permitted, in moving down great banks toward reaching the rich bedded gravel. On Humbug creek the miners are also busy, and have an abundance of water for ground sluicing and hydraulic mining, and the prospects of a big supply all summer from the west are very bright. The miners are busy with a better supply of water, and are working every day, Sundays included, and some of them nights also, when the weather permitted, in moving down great banks toward reaching the rich bedded gravel. On Humbug creek the miners are also busy, and have an abundance of water for ground sluicing and hydraulic mining, and the prospects of a big supply all summer from the west are very bright.

TRINITY.

THE OUTLOOK.—*Trinity Journal*, Feb. 19: In a mining point of view the present winter is decidedly the best experienced in this section. The water supply commenced earlier than usual and has kept up continuously, with a certainty of lasting longer than for many years. The mountains are covered with snow many feet deep, and we would not be surprised to see some on Old Baldy later next summer than ever before. The storms have come with such regularity and at such op-

portunity times, that we don't believe the miners themselves could improve on the present season, even had they the power to control the elements. Cold weather has not in the least interfered with the working of the mines, and in fact, everything in the weather line has been just as good and beneficial as possible. The miners, on one end of the county to the other, are improving their time and the splendid opportunities presented by the favorable season. Many of them run continuously, and there are none but who have done much more work already than all of last year. As indicated by the few partial clean-ups so far made, our mines should yield as much this season as they have during the past three or four combined. Certainly a claim which will not pay under the present favorable circumstances had better be abandoned. The "oldest inhabitant" has never experienced a mining season which in point of excellence could be compared to this. Let us be thankful, and joyfully await the result.

LEWISTON MATTERS.—The miners at Lewiston are all running with a full supply of water. This promises to be an exceptional year with the miners of that locality, who will not only meet the present favorable circumstances but will have found a deep back channel on one of the bars of Deadwood creek, which prospects excellently. We hope "Duffy" will not be disappointed in his expectations. Paulsen & Christensen will convey their Rush creek water across the river this summer, to be used on the property recently purchased from Harrison Fox. The water will be used for irrigating in the summer months and leased to miners during the winter. They will convey it under the river through iron pipes sunk in the bedrock, forcing the water through by hydraulic pressure, and giving it about 25 feet fall. They intend after preparing the pipe with coal tar, to sink it in the ground the entire length, holding that it will not be so subject to atmospheric influences by this procedure. They estimate that about 1,500 feet of 15 inch pipe will be required.

TUOLUMNE.

LADY WASHINGTON MINE.—*Sonoma Democrat*, Feb. 14: This mine, situated near Summerville, will commence running on Monday next, there being about 300 tons of rock out for crushing and the mill working 10 stamps. Calhoun Dorsey, Esq., the owner, has constructed a tramway of wire 2,400 feet in length, from the mine to the mill, the former being 750 feet above the latter, by which cars can be sent down every four minutes, being hauled back with a dummy engine. When Mr. Dorsey first proposed this continuous unsupported wire tramway, everybody predicted that it would be a failure. The distance they said was too long, the weight of the wire alone was sufficient to break it, and as for running loaded cars over it, that was impossible. They take it all back now and gaze with wonder at the novel spectacle of a box full of ore swinging through space along 2,400 feet of wire. Mr. Dorsey intended to place another wire in position shortly, so that loaded cars going down can return the empty cars to the mine. The mine is looking well.

Nevada.

WASHOE DISTRICT.

SAVAGE.—*Gold Hill News*, Feb. 17: Every effort is being made to reduce the water in the shaft. During the fore part of the week it seemed as if the pumps and hoisting tanks would be successful, as the water was lowered some 30 or 40 feet in the shaft. Yesterday, however, the water again rose to the 1800-ft level, where it yet remains.

KOSUTH.—Sinking the shaft is making excellent progress, the bottom in good blasting ground. The main south drift, at the 350-foot level, is made up of quartz, the face of the quartz and ore of a much better character than any heretofore encountered on that level. This drift does not have very much further to run to reach and tap the chimney of good ore found on the level above.

YELLOW JACKET.—The east cross-cut from the bottom of the south winze on the 1540-ft level is in 74 feet. The small cross-cut going east from the latter drift, connecting with the north and south winzes is in 42 feet. The east cross-cut from the bottom of the north winze, on the 1940-ft level, is in 120 feet. The faces of these several drifts are all in porphyry carrying occasional seams of quartz.

AMAZON AND GLACIOW.—Grading and enlarging for the foundation of a larger hoisting engine, and more extensive pumping machinery is making rapid and the most possible. Nothing further can be done in the mine until the machinery is ready to extract the water struck a few days since.

CALIFORNIA.—Sinking the winze below the 1500-ft level, in cross-cut No. 5, 100 feet south of the north line, is making excellent progress, the bottom still in ore. The small cross-cut reaching the 1550-ft level, is to continue directly downwards as an air winze for an indefinite depth, and will make the third winze sunk in the great ore body below the 1550-ft level. The first was on the Consolidated Virginia ground, and was sunk to a depth of 148 feet below the 1550-ft level, all the way in rich ore. The second was sunk 100 feet from the south line of the first ore body, and was sunk to a depth of 127 feet also in rich ore. The sinking of both of these winzes was stopped by water. The main north drift on the 1550-ft level, known as drift B, running to connect with the winze being sunk below cross-cut No. 6 on the 1500-ft level is being pushed vigorously ahead, the face in ore, the richness of which we may almost say is without a parallel, even in the rich ore of the Washoe district. The face in quartz and ore is being pushed to completion with all the energy possible. A large and commodious office is being erected near the works. The new air compressor is nearly ready to start up, and everything is fast assuming the best shape possible for a good spring and summer work.

UTAH.—The main west drift on the 400-ft level is badly caved, cutting off the ventilation afforded by the old upper shaft. The repairs to this drift are progressing rapidly, and it will not take long now to fully restore the old means of ventilation, and have everything in that portion of the mine again in good working shape.

RED AND WHITE CROSS.—Sinking the shaft is resumed. The shaft is being pushed ahead, the bottom indicates a near approach to paying ore. A contract is let for the requisite timbers, and as soon as they are received they will be put into the shaft.

JULIA.—Sinking the shaft was stopped during the fore part of the week, on account of having reached the full length of the present cables, others having been ordered. The new cables are being made in quietness, and have been built purposely for the reception of the new cables as soon as they arrive, which will be in a day or two more. This shaft has now attained the depth of 1680 feet, being the deepest perpendicular shaft on the lode. The main southwest prospecting drift on the 1600-ft level is advancing at the very rapid rate of eight feet per day, the face in quartz and ore being pushed to completion with all the energy possible. A large and commodious office is being erected near the works. The new air compressor is nearly ready to start up, and everything is fast assuming the best shape possible for a good spring and summer work.

LADY BEXAN.—Sinking the main shaft is going ahead rapidly, with no new or important features to report. The two west cross-cuts on the 170-ft level are steadily advancing, No. 1 still showing some excellent ore. On the 350-ft level the face in quartz and ore is being pushed ahead, while at the same time five cross-cuts are being run at different points to cut and prospect the ore vein. It is confidently expected that one of the drifts will in a very short time penetrate the ledge immediately under where the rich ore has been opened on the levels above, when some good developments may well be looked for.

CAWON POINT.—The main south drift on the 1600-ft level is steadily advancing, without any particular change to note during the week. The south winze, descending from the 1500-ft level to connect with this drift, will complete the connection in about 10 days, it yet having about 16 feet to sink to reach the 1600-ft level.

LADY WASHINGTON.—Sinking the shaft is resumed, and lively and effective work is being done working four six-hour shifts. A large amount of water comes in, but the powerful pumping apparatus disposes of it with the utmost ease. With the machinery, spacious and excellent buildings, fine, large, well located shaft and very encouraging developments, the present and future prospects of the Lady Washington mine are very favorable.

CALEDONIA.—Sinking the shaft has been considerably impeded during the past week by the steady, strong flow of water at the bottom. The water is handled with ease by the pumps.

SERRA NEVADA.—The north and south drifts, on the 1000-ft level, are making good progress. Both the south and north drifts, on the 700-ft level of the old shaft, are being driven vigorously forward. The face of each is in ledge material of a favorable character.

UNION CONS.—The north drift on the upper tunnel level is being driven steadily forward, following a fine streak of ore struck a few days ago. This streak of ore is from 10 to 18 inches in thickness, and is of a good quality and may yet lead to a large and valuable development.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is making steady progress, the rock in the bottom blasting out finely. The east drift on the 1050-ft level is pressed steadily forward, the face in a very favorable formation, with strong indications of soon reaching the ore vein. The pumps are working well, and everything is in excellent order for a strong flow of water should it be encountered when the ledge is reached.

JUSTICE.—Good prospecting and ore development continues to be done at the 400 and 600-ft levels. The winze being sunk from the 600 to the 800-ft level will be completed to connection in two or three weeks longer, at the present rate of progress.

THE FLORENTINE.—The slow and slackened sufficiently to admit of a resumption of work in the face of the main east drift on the fourth station level. Sinking the main incline is going steadily forward, the rock in the bottom still being quite hard, and the water causing considerable trouble.

MINZ.—The putting in of the several stations in the pump shaft is making rapid progress. It has been found necessary to refit some 60 feet of the main shaft, where the timbers were pressed in by the heavy body of clay through which it passed.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. There is little or no change whatever in the general appearance of the ore breasts or quality of ore extracted. The north drift on the 2000-ft level is steadily advancing at the rate of four feet per day, the face in very favorable ledge material.

NORR DAVTON.—This is a very promising mine. It is situated just north of, and adjoining the Dayton mine. A tunnel has been run nearly 600 feet in length, cutting the ledge and exposing some fine ore.

ROCK ISLAND.—The shaft is down to the 850-ft level, at which point a pump station is being put in. As soon as the pump tank is completed, a station will be opened and a drift started at that point to cut and prospect the ledge.

HALE & NONCROSS.—For a day or two during the week the pumps and tanks gained on the water, lowering it a number of feet in the shaft, but yesterday the water rose in the shaft in spite of all opposition; and this morning it has reached a point above the 1800-ft level, as high as it has ever been, and has heretofore risen.

SUCCESS.—Sinking the shaft has been considerably delayed by the repairs to the pumping machinery, so that no headway has been made in that quarter during the week. The main west drift on the 550-ft level is showing some very favorable indications of ore.

CAROLINA.—The shaft is down to the 400-ft level, the average value of which is \$27 per ton. The Combination shaft is making steady downward progress.

NIAORA.—This mine is being put in good working shape, and will be started up in a very short time under the able management of S. L. Jones, the superintendent of the Crown Point.

PROSPECT.—The development of this mine is being pushed forward with great activity, and sinking the shaft and running the drift goes ahead with a will. The small rich streaks thus far passed through by the tunnel show conclusively that a large rich vein or body of ore is very liable to be met with at a greater depth, and that is what the shaft is intended to develop.

THE SHAFT.—The shaft is now down 350 feet. The flow of water is quite strong. Preparations are being made to put in pumping machinery of the same size and character as that employed in the C. & O. shaft.

PAUL SHERIDAN.—This company has purchased, for the sum of \$12,000, the titles of several contending claims, and are now at work repairing the hoisting works building with the intention of the development of the mine in good earnest. Mr. S. L. Jones is superintendent.

SULLIVAN.—Very excellent ore assays and prospects have been met with during the week in the east cross-cut from the main south drift. No sign of any east wall yet, the drift continuing in the regular vein matter. The eastern portion of the great fissure seems to be the main vein, and the drift is being run in that direction as by no means improbable.

DAVTON.—The north and south drifts on the 500-ft level are steadily advancing, running parallel with the ore vein. The pump station and hoist-pit at the 400-ft level are nearly completed.

SILVER CITY.—The ore slopes from the upraise, both north and south, are yielding plenty of good milling ore, which is accumulating on the dump. Another upraise is being made, 150 feet farther to the southward, in the vein, showing four feet of good milling ore. Will commence shipping ore to the Ramsdell mill to-morrow.

NEW YORK CONSOLIDATED.—The west cross-cut on the 800-ft level is being pushed ahead with all the energy possible to cut the ore vein.

BULLION.—Sinking the incline is going steadily ahead at the rate of four feet per day. The upraise from the 1700-ft level, to connect with the bottom of the incline, is making excellent progress.

NORTH CARBON.—Very satisfactory progress continues to be made sinking the shaft below the 200-ft station. The main north drift at the 100-ft level shows a continuation of the good ore heretofore mentioned.

ROVER AND READY.—The shaft is now 60 feet deep, and Superintendent Caldwell is sending it downward as fast as practicable. During the recent stormy spell of weather the work was kept going tight straight along.

SEATHAN.—Shaft sinking at the usual good rate of progress, the machinery working finely and no water to interfere. Another level is to be opened when the proper depth is attained.

OVERMAN.—Sinking the shaft is making steady progress, notwithstanding a strong flow of water from the bottom.

THE MEXICO.—Very good work is being done grading for the heavy new machinery and getting it into place. The new works will be ready to start up about the middle of next month, when sinking the shaft deeper will be resumed.

NORTH CONSOLIDATED VIRGINIA.—Sinking the shaft is making good headway, the rock in the bottom working quite soft. Stringers of favorable looking quartz are frequently encountered.

BEST AND BELCHER.—The double winze below the 1500-ft level is repaired to within 12 feet of the 1700-ft level. The water is being hoisted from the 1700-ft level by the tanks of the Gould & Curry shaft, and is reduced

(Continued on Page 140.)

The Origin, Manufacture and Uses of Brass.

A contemporary contains, under the above title, the following historical data concerning this useful alloy: "Brass was common in Egypt long anterior to the exodus of Israel, for during that nation's journey to Canaan, the Israelitish women contributed their brass mirrors, which they brought with them out of Egypt, when brass was needed to make the brazen laver. The fact that the Egyptians were able to burnish brass so highly as to give perfect reflection of the 'human face divine,' would indicate not only great skill, but a large experience in its manufacture and use. Five hundred years after this time, Hiram of Tyre cast two pillars of brass—Jachin and Boaz—for the portico of Solomon's temple; these were more than 35 feet high, and some five or six feet in diameter. So valuable was the brass of which these pillars were composed considered, even by the Babylonians, when the pillars were nearly 500 years old, that during the destruction of the temple by Nebuchadnezzar, his soldiers broke them up and carried the material to Babylon to increase the richness of that great city. Among both the ancients and the moderns, brass has always ranked high among the useful and the ornamental metals.

"As early as 1750, mills and machinery for rolling and slitting iron were in operation in the United States. The first of which we have any record were put up in Middleboro', Hanover, and Milton, Mass.; but not until 1802 was such machinery called into requisition to roll brass and more readily to make it useful. At that time Abel Porter & Co. started a brass hutton manufactory in Waterbury, Conn. This firm had their brass ingots partially rolled in an iron rolling mill, and then completed the process by means of small rolls, driven by horse-power, in their own mill."

The article does not describe the manufacture of brass, and as practically this is of much more importance than any curious historical recollections, we will proceed to supply the deficiency. Brass is nothing but copper, of which the softness has been diminished, the melting point lowered, and the red color more or less changed to a golden yellow by the addition of zinc. The various proportions of the two metals give, as might be expected, various qualities to the brass. The addition of very little brass, say from one to eight per cent. to the copper, does not produce much change in the latter metal, except that such an alloy can be cast, which is not the case with pure copper, of which therefore, castings are seldom made, as it cannot be cast sound. The common practice among founders is to add an ounce of ordinary brass to every pound of copper to be cast. The addition of from five to seven per cent. of zinc to copper produces the gilding metal for common jewelry, while the reddish sheet brass produced at Hegermuhl contains, according to Ure, 13 per cent. of zinc. The pinchbeck, Manheim gold, Similor, and other alloys of various names, contain from 15 to 20 per cent. of zinc, while for bearing solder well, an addition of from 25 to 30 per cent. of zinc is necessary, the so-called Bristol brass consisting of this proportion. Emerson's patent brass was made of the constant proportion of 33 1/2 per cent. of zinc, or one part of zinc to every two parts of brass, while Mun's sheathing for the bottoms of ships contains from 37 to 40 per cent. of zinc. He says in his patent specification that any alloy between 50 of zinc to 50 of copper and 37 of zinc to 63 of copper will roll and work at a red heat, but that 40 per cent. of zinc to 60 of copper is the best; 44 per cent. of zinc to 56 of copper is the so-called spelter solder, used for soldering copper and iron; but to take 50 per cent. of zinc (equal parts) is generally considered better, as during the process of melting much of the zinc is always lost, it being quite volatile.

It is well known to practical men that spelter solder is found in the trade in a granulated form. The way to produce it in this form is to pour the alloy of equal parts of zinc and copper into an ingot mold with cross ribs, which incite it into little squares of about two pounds weight. These squares are then heated over a charcoal fire to nearly a cherry-red, and then broken upon an anvil, or with an iron pestle in a mortar. The right degree of heat is a very important point, as when too hot the solder will not crumble, on account of its roughness, but is beaten into a cake or coarse lumps, and becomes tarnished; when not hot enough, it will not break up at all; by a proper heat, it becomes nicely granulated, retains a bright yellow color, and is afterwards passed through a sieve. The ultimate proportion is less than 50 per cent. of zinc, by reason of the loss referred to.

The so-called patent Mossaic gold of Parke contains from 52 to 58 per cent. of zinc, and is dark colored when first cast, but becomes of a beautiful yellow tint when dipped in acid. From 60 to 70 per cent. of zinc for 40 to 30 of copper is a blueish-white brittle alloy, very brilliant, but so crystalline that it can be pounded cold in a mortar by a pestle. Lastly, 80 or 90 per cent. of zinc to 20 or 10 per cent. of copper, is hard and crystalline, and differs little from zinc, except that it is much stronger and more tenacious.

It is evident that from the volatility of zinc a very exact definite proportion can not be well obtained in melting; the fusibility increases exactly in proportion to the amount of zinc used, but not the yellow color; the red color of copper scarcely changes by the addition of less zinc than 20 per cent. to 80 of copper; at 25 per cent.

of zinc it slides into that of yellow brass, and remains nearly unaltered until the addition of some 40 per cent. of zinc, when it becomes whiter; until the addition of 65 per cent. of zinc to 35 of copper, the alloy has the brilliant silvery color of speculum metal, while by a further increase of zinc it adopts a bluish tint.

The ductility and malleability is nearly fully retained in all proportions from the pure copper until 40 per cent. of zinc is used against 60 of copper; additional zinc causes brittleness. The very best brass for all practical purposes, and which will file and turn well, consists of 20 per cent. of zinc to 80 of copper, and 36 of zinc to 64 of copper. This range is wide, but beyond this it does not work well; with more zinc it is too hard and crystalline, with less zinc it is too brittle or greasy, and hangs to the file like copper.

We ought to add here that before zinc was known as a separate metal, brass was made by adding to the copper, during the process of its fusion, a quantity of ore.

Eberhardt & Aurora.

We are informed that Captain Frank Drake, superintendent of the Eberhardt & Aurora company, will take his departure to-morrow for London, and will be absent two or three months. During his absence the captain's brother will superintend the affairs of the company. We have known some time that he contemplated a visit to London for the purpose of consulting with his company in regard to more extensive mining operations. His company will no doubt give him a very hearty greeting for the able manner in which he has placed them on the high road to prosperity. When Mr. Dreke undertook the superintendency of their affairs he found them in a deplorable condition and the company almost in a state of bankruptcy, and with little inclination to invest any more capital. In little less than a year he rebuilt the 30-stamp mill, which had been burned to the ground, and placed a large number of men in the mines, which became very remunerative, and in nine months' time paid all the indebtedness both of his company in London and White Pine, which aggregated no very small amount. After having accomplished all this, with a limited amount of capital and in so short a time, his company should esteem him as a competent and trustworthy superintendent, which we have no doubt they will do in a very substantial manner. We have not the least hesitation in saying that Capt. Drake has more executive ability than any other mining superintendent ever employed in Hamilton. There are few men, if any, who could have accomplished under the same circumstances what he has done. We hope he will succeed in convincing his company of the necessity of running a tunnel through Treasure hill, the economy of which must be apparent to them when properly explained. During his absence a great amount of prospecting and mining will be done on the several mines of the company, so that in the spring, when hauling can be done, the mill will be started up for an uninterrupted run of the year. The mill is now undergoing general repairs, and when completed will in all respects be equal to a new one. We wish the captain a safe and pleasant visit to London and a speedy return to his old friends here.—*White Pine News*.

MEASURING BY THE EYE.—Years ago, says a correspondent of the Boston *Transcript*, when we went to school in a little weather-beaten schoolhouse, what exciting contests there used to be over the teacher's favorite exercise of having the scholars estimate with the eye the size and weight of different objects in the room! He would hold up his cane, and have each one tell how long he thought it was, and it was a lucky child that could come within half a foot of the right length. He would measure an archin and then have the scholars try to reproduce the measure on the wall. He would mark off an inch or a foot or a yard in some conspicuous place, and then see how near anybody could come to chalking the same length on the blackboard. And it was astonishing how wide astray one would go. The fact is, our eyes deceive us ridiculously even upon the commonest things. At first thought, which should you say was the taller, a three-year-old child or a flour barrel? And could anything but actual measurement convince you that the same child is half as high as a six-footer? There is an old saying that a child two years old is half as tall as he ever will be; and after a few experiments in measuring one can easily believe it, but not before.

TIMBER LANDS.—Senator Kelly's bill for the sale of timber lands in the States of California and Oregon and in the Territories of the United States, has been reported favorably by the Senate Public Lands Committee without amendment. It provides that certain surveyed public lands in California, Oregon and Washington Territory, valuable chiefly for timber but unfit for cultivation, may be sold in tracts not exceeding 160 acres to any one citizen or association, at the minimum price of \$2.50 per acre. For the other Territories the size of the tracts is limited to 40 acres. The bill is a copy of the measure recommended by the Public Lands Committee of the House of Representatives (based on Mr. Page's public land bill). It may be remembered that it contains a number of stringent requirements for oaths and affidavits to prove the character of the land, and that it is purchased for individual use and not for speculative purposes.

San Diego Mines.

A correspondent of the San Diego *World*, writing from Julian City, says:

Thinking that a few items from the mining section would be of interest to the readers of your paper, I pen the following: We are experiencing one of the heaviest storms that has visited Julian and vicinity for the past six years.

Weather, Snow, Etc.

On Thursday afternoon about four o'clock it commenced snowing. On the following day, at 12 o'clock, the snow measured 18 inches in depth. The snowfall is about three feet, but for the past 36 hours it has run off as fast as it fell. At present there are about 12 inches on the ground. This evening the weather has moderated, it growing much warmer and a light rain falling. Should it continue to rain till to-morrow, you may look for a flood about Old Town, as the snow will have melted by that time, making a fearful rise in the San Diego river.

Farming, Etc.

The farming interests in this vicinity are safe this season, as there has been sufficient rain to insure abundant crops, and one will observe a smile of satisfaction playing upon the features of the sturdy husbandman of this section.

The Mines.

The mines are progressing steadily and developing beyond the expectation of the most sanguine.

The Helvetia.

The Helvetia, one of the pioneer mines of the district, has the main shaft 300 feet deep, with levels drove, east and west from the bottom of the same respectively, 100 feet. The ledge averages three and one-half feet in width of very fine ore. With a force of 20 men this company are enabled to keep their 10-stamp mill running day and night. The amount of ore in this mine is unlimited, and under its present system of working cannot otherwise than prove remunerative to its owners. One conversant with mining, observing the condition of this mine, and the machinery employed in operating the same, will be convinced that the Count, the present superintendent, understands his business as a mining engineer.

The Tom Scott

Company have their shaft down 150 feet, and are now driving a level west on the ledge to connect with the air shaft. This level is now about 40 feet from the main shaft, showing three feet of ledge—three tons of which was crushed at the mill of the Helvetia company, a short time ago, for a test, which yielded \$35 per ton. When this company make the connection between the two shafts, which are 100 feet apart, they will have an immense body of ore above the 150-ft level to stoop out.

The Pride of the West.

Owned by Fred. Beck & Co. They are prospecting work on their mine, which gives promise of taking rank with the leading mines of this district. Seventeen tons of ore crushed from this mine, a few days past, yielded \$48 per ton.

Hidden Treasure, Big Blue.

A lot of rock was recently crushed from the Hidden Treasure and the Big Blue, the former yielding \$80, the latter \$85 per ton.

So RAPID has been the course of business between the two greatest of American cities—New York and Philadelphia—that notwithstanding the great efforts made in every way possible by the old companies, it was thought they would soon be taxed beyond their power entirely. Soon, however, the traffic will be better met, for we are told that: "The new railroad from New York to Philadelphia is nearly completed, and will soon be in operation. The length of the 'New York and Philadelphia New Line,' from Liberty street in this city to Berks street, Philadelphia, is 88 miles. The distance will be accomplished in one hour and fifty minutes."

A REMARKABLE example of rapidity in deep boring has recently been furnished by the first bore-hole put down by a company formed to search for coal in Switzerland. A depth of 1,422 feet was reached in two months, including the re-boring of the upper 640 feet from three and one-eighth inches to seven inches in diameter. The work was done, including all delays, at a rate of over 1,000 feet per month, the highest speed being nearly 77 feet in 24 hours. The results obtained were negative, the section showing about 1,200 feet of permian strata resting upon old crystalline rocks; but the trial is only the first of a series.

SPEAKING of the coal mines near Uter City, Coos county, Oregon, the *News* says: "The vast amount of coal which lies imbedded in these hills is almost incredible. The foreman and the miners say the outcrops of eight good workable veins are distinctly visible on the side of the mountain owned by Uter & Ojeda. Each one of these veins is a mine of itself, and can easily be made to produce 150 tons daily—the product of the eight veins thus aggregating a total of 1,200 tons per day."

A lot of bullion worth \$9,000 was shipped from the Virtue mine the other day, by way of Boise and Silver City, but the express agent, fearing mischief, held the bullion over one day, thus disappointing the robbers, who had evidently been informed of the proposed shipment, as they stopped the very stage on which it would have been had it not been delayed.

English vs. American Workmen.

In pursuance of instructions, United States consuls in Europe have been supplying to their government some information relating to the laboring classes, and the chief of the Bureau of Statistics has published the result of the inquiry. The general conclusion to be drawn from the answers is unfavorable to the efficiency of English labor as compared with American. It would seem that nine hours of an American's labor are equal to about ten of an Englishman's, the superiority being nearly represented by the ratio of 10 per cent. The consuls at Bradford, Sheffield and other manufacturing cities, and the chief of the bureau himself, came to this conclusion after much investigation. This is especially true of heavy manufacturing work, such as machine and engineering work and the fabrication of hardware, cutlery and other manufactures of iron and steel. In all these branches 900 Americans are thought to be equal to 1,000 Englishmen in the amount of work per week they will accomplish.

This corresponds with the experience of our own manufacturers. It has before been observed here that in labors demanding enormous physical strength and endurance—like iron puddling—the Americans were superior to the English; while in patient, steady drudgery the British "navvy" or Irish day laborer is much beyond the Yankee; and Mr. Brassey's experience is no doubt true, that the English day laborer is the cheapest laborer in the world, because he accomplishes the most for the money. The American demands a toil with some peculiar stimulus to call out his best powers. Thus, in a dangerous, difficult employment like lumbering, demanding great strength and presence of mind, no nationality is equal to the American. The superiority, however, of which we have spoken, seems to be less true in other branches, and in cotton and woolen manufacture the British superiority is expressed by the ratios of eight and six per cent.

The explanation given by the report of the greater efficiency of American labor is probably the true one—that it lies in its greater "adaptability," owing to the superior education and intelligence of the American factory workman, and in more temperate American habits. The English workman requires a day or two to get over his Saturday night and Sunday night drinking sprees. The extent to which the English laboring class drink up their wages appears in a melancholy form in this report. The consul at Sheffield reports that great numbers of working men stop work on Saturday noon, and do not commence again till the following Wednesday. This is, in part, because they need Monday and Tuesday to enable them to recover from the effects of Sunday's drinking. "Increase of pay," says the consul at Birmingham, "means increase of drink." In Manchester, our consul reports that many sober working women complained that increased wages and shortened hours of labor were a curse to the families, as the men were only more tempted to drink. In Liverpool there seems a widespread and fearful demoralization of the laboring class from their intemperate habits. And thus from almost all the manufacturing centers our officials report a wretched condition of workmen's families and reduced efficiency of labor from the habits of intemperance prevalent.

A curious fact also appears in these researches, namely, that a rise of wages does not always produce more work. Thus in the collieries of Leeds the product for each person in 1864 was 327 1/2 tons for 313 working days, or 21 1/2 cwt. for each person per diem. In 1868 it fell to 317 tons, or 20 cwt. per diem; in 1873 to 17 1/2 cwt. for each person per diem. That is a reduction of production in 10 years of 19 per cent., while wages have risen 30 per cent. and upward. In Manchester the average earnings of a certain mine were four shillings seven pence per day in 1871; in 1872 the wages had more than doubled, and yet the earnings were two pence less per week for each man. The workmen averaged less than four working days per week, while many only worked three days. The statistical proof presented by the United States Bureau of Statistics of the terrible loss and degradation to the English laboring classes produced by their drinking habits will not be one of the least of the good results accomplished by this able report.—*Iron Age*.

MACHINE SHOPS IN RUSSIA.—In 1866, Russia had 100 foundries and machine shops, only 52 of which were provided with steam. At the present time there are 362 of these establishments, 79 of which are exclusively occupied with the manufacture of agricultural implements. Statistics are to hand concerning 179 shops only; these employ 46,528 workmen. In 1868 there were 222 locomotives made in Russia; last year the number was 768. A large number of English workmen are employed in Russian engineer shops, but they complain of being treated as naturalized Russian subjects—that is to say, their personal rights and liberties are but little respected.

The bullion product of the Boston and Colorado smelting company, at Black Hawk, Colorado, has been \$28,500 in silver for the past week, the gold ore being shipped to Boston. The letter part of this month the mill will commence the treatment of gold ores, and will continue transactions in that line during the year. Professor Hill, the manager, anticipates that the product of the works for the year will amount to \$3,000,000.

USEFUL INFORMATION.

Hints on Familiar Things.

Why is a ray of light composed of various colors? As every ray of light is composed of all the colors of a rainbow, some things reflect one of these colors, and some another.

Why are some things of one color, and some of another? As every ray of light is composed of all the colors of a rainbow, some things reflect one of these colors, and some another.

Why do some things reflect one color, and some another? Because the surface of things is so differently constructed, both physically and chemically.

Why is a rose red? Because the surface of a rose absorbs the blue and yellow rays of light, and reflects only the red ones.

Why is a violet blue? Because the violet absorbs the red and yellow rays of the sun, and reflects the blue only.

Why is a primrose yellow? Because the surface of the primrose absorbs the blue and red rays of solar light, and then reflects the yellow ones.

Why are some things black? Because they absorb all the rays of light, and reflect none.

Why are some things white? Because they absorb none of the rays of light, but reflect them all.

Why are the leaves of plants green? Because a peculiar chemical principle, called chlorophyll (signifying green leaf), is formed within their cells; which has the property of absorbing the red rays, and of reflecting the blue and yellow, which (being mixed together) produces green.

Why are some things transparent? Because every part between the two surfaces has a uniform refracting power, or (in other words) has in every place the same density, and, therefore, the rays of light emerge on the opposite side.

Why are some things not transparent? Because the particles which compose them are separated by minute pores or spaces, which have a different density from the particles themselves. Therefore, the rays of light are too often reflected and refracted to emerge.

A SIMPLE WAY OF PROCURING FRESH WATER FROM SEA WATER.—A method of procuring fresh water from sea water through the direct action of the sun's rays is among the foreign inventions. The apparatus consists of a box of wood one inch thick, about 14 feet long, two feet wide, and an average depth of six inches. The upper part of the box is closed with ordinary glass, which has an inclination of an inch and a half. At the lower edge of the glass there is a semi-circular channel, destined to receive the fresh water which is condensed on the interior surface of the glass. The operation is entirely simple. The salt water is let into the box for about an inch in depth, and then it is exposed to the rays of the sun. A very active evaporation then begins, and it is found that a square meter of glass will condense daily the amount of two gallons of pure water.

PRESERVING WOOD BY THE APPLICATION OF LIME.—The method of preserving wood by the application of lime, as pursued by M. Stovall, is published in the French journals. He piles the planks in a tank, and puts over all a layer of quicklime, which is gradually slacked with water. Timber for mines require about a week to be thoroughly impregnated, and other wood more or less time according to its thickness. The material acquires remarkable consistence and hardness on being subjected to this simple process, and, it is alleged, will never rot. Beech wood has been prepared in this way for hammers and other tools for iron works, and it is said to become as hard as oak without parting with any of its well-known elasticity or toughness, and to last much longer than when not thus prepared.

BAO MARKING INK.—A correspondent of the *English Mechanic* gives the following recipe for an ink, the permanency of which he says is perfect, even when bags filled with chemical manures have been in rain and sunshine for ten days: Boil one pound of logwood chips in one gallon of water, at boiling point, ten minutes; then stir in the eighth of an ounce of bichromate of potash, and boil this 10 minutes longer; then add, when cold, one-half pound of common gum, dissolved, and stir well in. This will flow well from the pen, and will mark bags with either the stencil plate or block. The cost of the above ink is about 12 cents per gallon.

The first houses with glass windows mentioned in history, were erected in the ancient city of Tyre, in Syria. The first plate glass made in England for looking-glasses, coach windows, etc., was made at Lambeth, in the year 1673.

AN OAKEN COLORED can be given to pine tables by washing them in a solution of copperas dissolved in strong lye, a pound of the former to a gallon of the latter. When dry, this should be oiled, and it will look well for a year or two; then renew the oiling.

AFTER filing a saw, place it on a level board and pass a whetstone over the side of the teeth until all the wire edge is off them. This will make the saw cut true and smooth, and will remain sharp longer. The saw must be set true with a saw set.—*Scientific American*.

ANOTHER NEW ELECTRIC BATTERY.—This apparatus, invented by two Frenchmen, is contained in a square glass jar. The pile is composed of a prism of charcoal which contains sesquioxide of iron in its pores, and a small rod of amalgamated zinc. The latter passes through the stopper, to the nuder surface of which is fixed the charcoal. A solution of ammonium chloride is used as the exciting fluid. The reactions are the same as in Leclanche's couple, in which oxide of manganese is used. When the circuit is closed, the chloride of ammonium attacks the zinc, forming a double chloride of zinc and ammonium. The latter, on being set at liberty, decomposes the sesquioxide of iron, carrying off a part of its oxygen and forming free ammonia, which disappears by evaporation. This pile ceases to act so long as the circuit remains open. Its durability and force are large. Its electromotive power is as 12 to 10 of the sulphate of copper battery, and it is thus well adapted for industrial purposes.

MEASURES FOR MEN.—One thousand shingles laid four inches to the weather will cover one hundred square feet of surface, and five pounds of shingle nails will fasten them on. One-fifth more siding and flooring is needed than the number of square feet of surface to be covered, because of the lap in the siding and the matching of the floor. One thousand lath will cover seventy yards of surface, and eleven pounds of lath nails will nail them on. Eight bushels of good lime, sixteen bushels of sand and one bushel of hair, will make enough good mortar to plaster one hundred square yards. A cord of stone, three bushels of lime and a cubic yard of sand, will lay one hundred cubic feet of wall. Five courses of brick will lay one foot in height on a chimney; six bricks in a course will make a flue four inches wide and twelve inches long; and eight bricks in a course will make a flue eight inches wide and sixteen inches long.

CHANE chains should once in a while be taken off and thrown into a furnace until red hot, then brought out and be kept in a compact pile and permitted to cool slowly. Better still, let them remain in a furnace after coming to a heat and then to cool off with the furnace. Where a furnace can not be had for the purpose, they can be heated in a large wood fire and then be permitted to cool as slowly as the fire was dying. Being thus annealed they are safe.—*Am. Manufacturer*.

GOOD HEALTH.

Bicarbonate of Soda a Toothache Remedy.

Dr. Buckworth, of St. Bartholomew's hospital, London, has recently successfully used bicarbonate of soda as a remedy for severe toothache, when applications of chloroform, either externally to the cheek or to the ear, or placed on cotton in the decayed tooth, failed; and when carbolic acid, applied as last mentioned, also proved inoperative. Pledgets of cotton soaked in a solution of 30 grains of bicarbonate of soda in one fluid ounce of water gave almost instant relief. Dr. Buckworth considers that very frequently the pain is due to the contact of acid saliva with the decayed tooth, and therefore it is important, in cases of odontalgia, first to determine whether the saliva has an acid reaction. If this be the case, then a simple alkaline application, as above stated, is the most efficacious means of cure.

Cases of toothache are so common accompaniments to disordered stomach that there seems every reason for the truth of the above author's conjecture. Doubtless on the same ground is due the efficacy of ammonia, so frequently recommended, but which, if applied carelessly, is liable to produce more pain by burning the gum than already exists in the tooth.

Bicarbonate of soda is found in every kitchen, and hence no more handy remedy could be devised, while it is destitute of any painful effects; and the rationale of its operation and its simplicity make us wonder why it has not been thought of before.

KILLED BY A MOUSE.—A extraordinary occurrence was brought to light at an inquest held a few days since on the body of a man in South London. It appears that in a work room where many young girls were at work, a mouse suddenly made its appearance on the table, causing, of course, considerable commotion and a general stampede. The intruder was seized, however, by a young man who happened to be present, but the mouse slipped out of his hand, and running up his sleeve, came out between his waistcoat and shirt at the neck. The unfortunate man had his mouth open, and the mouse, on looking for some place of concealment, entered the man's mouth, and he, in his fright and surprise, swallowed it. That a mouse can exist for a considerable time without much air has long been a popular belief, and was, unfortunately, proved to be a fact in the present instance, for the mouse began to tear and bite inside the man's throat and chest, and the result was that the unfortunate fellow died, after a little time, in horrible agony. Several witnesses have corroborated the above facts, and medical testimony as to the cause of death having been given, a verdict of accidental death was returned.

Some Causes of Nervousness.

Imperfect and insufficient sleep is one of the most frequent causes of nervousness. In Realmah, that strange country which Sir Arthur Helps so quaintly describes, "tired nature's sweet restorer" could be bought in three grades of different prices, the costliest one being of a pale blue color. Partaking of this, the happy buyer sank into a profound and dreamless sleep, while the cheaper kinds procured only the lighter forms of rest, haunted by dreams and disturbed by thick-woven fancies. Next to air sleep is the greatest need of man. "Who sleeps eats," says the ancient proverb. Food and drink may be diminished without fatal results, but want of sleep is followed by insanity and death. Those who suffer from nervousness on account of inane sleep should lose no time in correcting the evil. Everything calculated to excite the brain or disturb the nerves for two or three hours before bedtime, such as stimulating beverages, hearty food, exciting conversation or literature, should be rigidly avoided. It is said that half a dozen small onions eaten just before retiring will act as a harmless anodyne, and induce profound and refreshing sleep.

Another fruitful cause of nervousness is bad air. Many a child grows pale and sickly from attendance, as is supposed, at school, and the parents think the child is studying too hard. In a large majority of such cases the evil results are the consequences of the impure air the child breathes, and would not follow twice as severe mental application in a room thoroughly and constantly ventilated. Doubtless a large part of the teachers who "break down" in teaching do so because of the bad air they breathe from day to day. Many a housekeeper would escape attacks of nervousness if she kept the windows up and the doors open, and let the sunlight pour into her rooms with healing in its beams.

Another cause of nervousness is indulgence in strong tea and coffee. The person who depends on his coffee as the main article of breakfast will be sure to eat less nutritious food at that meal than if his beverage were cold water; the nerves, only stimulated, but not fed, will by and by mutiny. The strength which comes from stimulating drinks of all kinds is fictitious, not real; it is a draft on the future that will be some time he presented for payment to an empty exchequer. *Delirium tremens* is nothing more than the cry of the wronged and cheated nerves for food.

Overwork often produces nervousness, and the cure is rest. Many people think they must go on killing themselves by slow degrees in this way, and when they have succeeded, lookers-on are no wiser than before, but keep on taxing themselves beyond their strength and paying the penalty. Of all the causes of nervousness the most prolific is worry. If, having done our best, we could only leave the consequences to the Higher Powers; if we could but be content to take life as it is and make the most of it; to do the duty of the hour promptly and with fidelity and think no more about it; to open our hearts to all the gentle influences of nature that woo us, and enjoy without murmur or question the good and the evil that fall to our lots, confident that they are alike beneficial, to live aright in the present and leave the future to God, what a world of trouble and anxiety we would be saved! Plenty of sleep, plenty of air, plenty of food, and an abounding trust in the goodness of God will keep those who enjoy these blessings from the tortures of nervousness.—*N. Y. Tribune*.

An Arsenic-Proof Stomach.

A thirteen-year-old daughter of a Mr. Flagg, residing near Whitehall, is exciting the attention of the physicians, and scientific men in that vicinity. Some time ago Flagg put some arsenic on some bread and placed it in a portion of the house frequented by rats. The bread suddenly disappeared, and again and again other pieces were placed in the same locality, with the same result. He finally determined to watch and ascertain, if possible, what became of it. He had not long to wait before he was horror-stricken to observe his little daughter walk away from the place, cramming her mouth with the poisoned bread. A physician was sent for, and before his arrival the sobbing child made known to her parents that she had eaten all the bread that had been prepared for the rats, and that she liked it better than anything she had ever tasted. The physician was surprised, and thinking, possibly, that the drug might not be arsenic, he examined it, and found it arsenic beyond a doubt. To still further test it he tried a small quantity of it on a cat, which quickly sent the animal into convulsions, causing its death very soon afterwards. What seems remarkable, too, is the fact that ever since the child first tasted arsenic it has begged for the deadly drug, time and time again. About a year ago the girl fell sick with fits. Nothing would bring her out of the convulsions. In her quiet moments she would beg incessantly for arsenic. The physician in attendance, believing that the girl could not possibly recover, ventured to give it to her. The child devoured it with avidity, and in less than three days she was as well as usual. Since then she has taken the deadly poison at different times, the only effect it having upon her being to make her appear well, bright and cheerful. The case has been laid before several scientific men, all of whom pronounce it one of the most remarkable phenomena of the age.—*N. Y. Times*.

DOMESTIC ECONOMY.

How to Wash Dishes.

Faith Rochester writes in the *American Agriculturist*: I dislike greatly to wipe dishes that have not been drained from clear hot water. Yet I seldom see any one wash and wipe dishes in my way. Usually the dishes are washed in suds, and then are either passed immediately through hot water and wiped by an assistant, or they are piled up and afterward are turned over in a dish-pan as though to drain them (over their backs), after which each is taken from the rinsing water and immediately wiped without previous draining. In either case the wiping cloth is made quite wet, and sometimes two or three are needed for the operation. I think it is a saving of labor, on the whole, to drain the dishes, though one has to use a common dish-pan for it, as I do. There is no other comfortable process if children do the work. A little girl, six years old, washes and wipes all of my breakfast dishes, and usually wipes the dinner dishes for me. She kneels in a chair at the dish-table and does her work very satisfactorily. I first wash the pans and stone or iron dishes, all of the big, awkward, or very sticky utensils, and my rinsing water serves as her dish water. I get the work all ready for her, placing the plates in the bottom of the dish-pan, with saucers, cups, etc., at the top, and knives, forks, and spoons stuck in around the sides. When I call her to the work, she finds these dishes soaking in warm water, with a clean, orderly table to pile them upon as she washes them. Sometimes I get the rinsing water for her from the stove reservoir, but if I am busy she gets it herself, if able to empty the big dish-pan of the dish water. The big pan is used for draining the dishes, after being wiped out clean with the dish-cloth. The rinsing water is in another pan, and the washed dishes are run through it, cups first, then bowls, saucers, plates, etc., and are all turned down to drain in the dish-pan. They dry very fast, and the wiping cloth is scarcely damp when the work is done. Some good housekeepers wipe the dishes directly from the first suds, but that never seems to me a clean way of doing.

"I always scald my dishes," boasts one, but I happen to know that her dishes are usually streaked or sticky when put upon the shelves, because she "scalds" them in such an absurd manner, turning them all down in her pan, and pouring hot water over the backs of her dishes, leaving the faces of the plates and other dishes unclean, while the heating they get from the hot water on their backs dries the suds or greasy dish water in streaks, which do not all wipe off; and so the wiping-towels get quickly soiled.

A Royal Dish.

I lately saw a picture and a description of a dish said to be greatly relished by Emperor Dom Pedro, from whom it derived its name. Now, I had no such pan or dish, but I was determined to contrive one. Therefore, I went to the kitchen press, took down the steamer—its bottom is loose, and can be taken out—took out the bottom and found that it would just fit the top of our smallest frying-pan or spider. Next day I contrived to have 100 many potatoes for dinner; these I placed on the steamer-bottom, making a smooth pyramidal shape of them, placed a bit of butter upon them, then put the gravy and meat scraps left from dinner in the spider, added a little water, and put the potatoes and steamer-bottom upon this and placed all in the oven of the cook stove. At supper my makeshift dish was heartily partaken of and praised, and I presume was as good as if I had possessed the real "Dom Pedro dish" to cook it in. The potatoes were baked a nice brown, the meat and gravy warmed over nicely, and the steam from the meat had gone into the potatoes, making them better than if baked in a pan.—*Carrie Lee, in Am. Patron*.

To prevent flat irons from rusting, melt one-fourth ounce of camphor and one-half pound of fresh hog's lard over a slow fire, take off the scum, and mix as much black lead with the composition as will bring it to the color of iron. Spread this over the articles for which it is intended. Let it lie for 24 hours, and then rub it well with a dry linen cloth. Or smear the irons over with melted suet, and dust thereon some pounded unslaked lime from a muslin bag. Cover the irons with baize in a dry place when not in use.

GINOEN CAKES.—Rub a quarter of a pound of butter into half a pound of flour, mix one egg, three ounces of powdered loaf sugar, and half an ounce of ground ginger with the butter and flour, and make them altogether into a paste; roll it out a quarter of an inch thick and cut it into round cakes, about two or three inches across; bake them in a warm oven, on iron plates.

A GOOD GRAVY.—Chop fine some lean meat, an onion, some slices of carrot and turnip, and a little toyme and parsley; put these with half an ounce of butter into a saucepan, and keep them stirred until they are slightly browned; add a little spice, and water in the proportion of a pint to one pound of meat. Clear the gravy from scum, let it boil half an hour, and then strain it for use.

Prompt Subscriptions.

We wish to thank those subscribers who send in
their renewals to the Press promptly as regularly as
the year comes round. It saves us much expense in
commissions for collections and renewals. May we not
request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this
paper to persons who we believe would be benefited
by subscribing for it, or willing to assist us in extend-
ing its circulation. We call the attention of such to our
prospects and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set
in solid type, giving in our columns one-third more
reading than is contained in ordinary leaded matter.

THE MINIMOTOR.—This is the name of a new
motor which is now being introduced in this
city by Huntington, Hopkins & Co., one of the
machines being in operation at their store on
Market street. This little motor is intended
as a safe and economical power for very light
work, such as running sewing machines, dental
engines, coffee and spice mills, fans for refrig-
erators and engines, small lathes, etc. The
minimotor uses compressed air for motive
power. It is made quite small, so as to be run
by the heat of gas. The one at Huntington &
Hopkins is a one-horse engine, and coal is used
for heating purposes. There is no boiler to
explode, as there is no steam, and the whole
thing is quite simple. We shall shortly give a
detailed description of this machine, with en-
gravings.

The excitement in Heidelberg over the dis-
covery near that place of rich gold and silver-
bearing rock is unabated. Assays are said to
run between \$900 and \$1,000 gold and silver
to the ton.

It is stated that a new vein of coal, 11 feet
thick, has been discovered on the Skagit river,
Washington Territory, by Messrs. Tracy and
Stevens, and is considered of a superior quality.

More sulphur discoveries are being made to
the westward of Steamboat Springs. They
have now found a very rich deposit that is
traceable for over a mile.

WILLIAM ROBERT DUKE, one of the survivors
of the "Light Brigade," which made the
famous charge at Balaklava, is in this city.

A Quicksilver Furnace for Fine Ore.

We examined recently a model of a new
style of quicksilver furnace, designed particu-
larly for roasting fine ore, but in which coarse
ore can be reduced as well. It is the invention
of Daniel Jones and Daniel Jones, Jr., of this
city. It is essentially a system of vertical in-
stead of horizontal retorting, which is accom-
plished in quite a simple manner. The in-
ventors are practical men and mechanics, hav-
ing constructed a number of quicksilver furna-
ces of different patterns. They have made note
of what seemed to them objections and diffi-
culties in other furnaces, which they have en-
deavored to overcome in a furnace of their own
design.

The furnace may be considered as a series of
retorts, as no flame comes in contact with the
ore. There are only three walls to construct, as
the smut chamber makes the fourth side. The
furnace is made of fire proof material, what
iron work there is being on the outside or cov-
ered in. On top of the furnace is a place cap-
able of drying from five to six tons of ore. An
elevator carries the ore up to the hopper on
top of the furnace, where it is fed in. On the
inside of the furnace are a series of inverted
V-shaped chambers or retorts, which are heated
by the fire. The fire is fed at the bottom and
the heat, flame and gases pass up around these
chambers, and as they are hollow, pass through
them too; but the flame in no place touches
the ore.

When the ore is dropped into the hopper it
falls on to the hot inverted V shaped chamber
and then into a hot V shaped receptacle. In
the bottom of this is a slide which draws out at
certain intervals and drops the ore into an-
other similar chamber, from which it in turn
drops into another, and so on until it reaches
the bottom. For a 20-ton furnace, which is
from 15 to 20 feet high, a double furnace would
have 10 of these chambers in each side. An
eccentric rod on the outside operates the slides
which allow the ore to drop from one chamber
to the other. This rod turns very slowly, and
it will take a charge of ore about 40 minutes to
drop to the bottom. Of course, as soon as the
ore drops out of the upper retort, another
charge is admitted. Each charge is about 100
pounds, so that there would be one ton at a
time in the furnace, and for each revolution of
the eccentric 100 pounds of ore would be
charged and dropped out.

In the sides of the furnace are air holes, or
holes to see the operation as the ore passes
down. If necessary fire can be put on the
inside of the V shaped chamber from these holes.
They also afford an opportunity to clean out
the chambers without taking out any brick
work. The eccentric rods are placed on both
sides. In a double furnace, as in this case,
there would be 10 chambers on each side, or 20
drops in all.

A stream of heated air is forced into the fur-
nace and into the ore so as to assist in the de-
struction of the sulphur and give more heat.
There is no place for the ore to catch and stop,
but as it falls on the heated surfaces, which are
all inclined, it slides on to another and so on
down, being slightly retarded by the slides;
which, however, allow it to drop to the lower
chamber at regular intervals.

The retorts are entirely closed from the
flames and gases, but are thoroughly heated,
nevertheless. The furnace is accessible at any
time without tearing down anything. Any par-
ticular chamber can be removed if broken and
another one replaced. The chambers are made
in sections, and expansion and contraction are
taken into account. All the iron is covered
with a material like enamel, which is fire-proof
and not affected by the sulphurous fumes. The
smut chamber is made in sections and in
case anything is wrong it can easily be examined
without pulling down any brick work. As no
flames get at the ore the formation of much
"smut" is prevented. In the bottom of the

smut chamber is a pipe, so in case any quick-
silver should collect, it can be drawn off. The
fumes pass into this smut chamber and then
into the condenser, any style of which can be
used. Messrs. Jones have, however, con-
sidered of their own design, which they con-
sider more effective than those now in use. An
engine runs the eccentrics which operate the
slides in the bottom of each separate retort.

The furnace, as before stated, is mainly for
fine ore and dispenses entirely with the neces-
sity of working adobe. A double furnace
with condensers, engine and all complete,
with a capacity of 10 tons, will cost about \$7,000,
ready to be put in motion. There are a num-
ber of advantages possessed by this furnace,
but it must be seen to be appreciated. The
construction is very peculiar and is difficult to
describe without the use of engravings. It is
worthy the attention of quicksilver miners,
who should examine the model themselves in
order to understand it thoroughly. The model
can be seen at room 80, Nevada block.

Foundry Notes.

After several months of comparative inactiv-
ity the foundries of the city are again engaged
in work on several large contracts. These con-
sist principally of mining machinery for the
Comstock mines, which seems to be needed
heavier and heavier from year to year. The
hoisting and pumping appliances for these
mines require great mechanical skill in their
manufacture, but our foundrymen have all the
requisite tools and ingenuity to carry out any-
thing of the kind proposed.

There was cast at the Union iron works last
week the largest cylinder ever made on this
coast. The cylinder is a portion of an engine
which is being made by Prescott, Scott & Co.
for the joint shaft of the Chollar, Hsle & Nor-
cross and Savage mines. It is a compound
pumping engine of 2,000 horse-power, with
Devy's differential valve motion. The weight
of the low pressure cylinder is 20 tons, and
that of the high pressure cylinder 10 tons. The
engine is designed to work double or single
acting. It is intended to be of sufficient capac-
ity to work 4,000 feet. The total weight of all
this machinery is 700 tons, and it is much
more powerful than any pumping machinery
now on this coast.

At the Pacific iron works they are now en-
gaged in making the mold for casting a cylin-
der but little smaller than the one above men-
tioned, to accompany some very heavy mining
machinery, of which we shall shortly give a
detailed description.

At the Risdon iron works they are now at
work on a very fine pumping engine for the
Belcher and Crown Point mines, to be placed
in the Belcher air shaft. This is to be a very
handsome piece of machinery, and when com-
pleted we will describe it in detail. It is a ver-
tical compound engine of 600 horse-power,
with one cylinder of 30-inch diameter, with a
10 foot 7-inch stroke; the other diameter of 62
inches and 8-foot stroke. The valve motion
will be controlled by Patten's improvement on
Devy's valve gear. By this important im-
provement, already tested on the 400 horse-
power engine at the C. & C. shaft, and on the
Ledy Washington machinery, a small engine is
used to run and control a very much larger
one, so that the large engine can be made to
perform a stroke in five minutes, or any num-
ber up to 12 strokes per minute, the engine
making the strokes in the same length of time
whether it be running fast or slow. The cost
of the new engine will be about \$400,000.

NEW ALMADEN.—Through the courtesy of
Mr. J. B. Randol, manager, we are able to
give our readers a tabulated statement, show-
ing the details of production of the New Al-
maden quicksilver mine for 23 years and three
months. As this is the most productive quick-
silver mine in the United States, these carefully
kept details are very interesting.

Improved Joint for Hydraulic Nozzles.

John J. Crawford, of this city, has recently
patented, through the agency connected with
this office, an improvement for connecting
nozzles to hydraulic mining pipes. The object
of the improvement is to so construct and com-
bine a ball and socket joint (with the water
pipe and nozzle) that will move easily under
pressure, be free from leakage, and present no
obstruction to the passing stream, especially
when the nozzle is deflected. It also embraces
an improved balancing device for sustaining
the nozzle at whatever elevation it may be
directed.

Upon the piece of timber or block upon which
the joint is supported is secured a casting which
has two standards, extending upward, one on
each side of the casting. The rear end of the
nozzle can either be formed into a socket or
the socket may be made independently or at-
tached to it. Between the two upright stand-
ards is mounted a ring by means of pivots or
journals, so the ring can turn freely about a
horizontal axis. Inside of this ring is placed
the socket, secured to it by pivots or journals
above and below, so that it will turn freely
about a vertical axis inside of the ring. The
socket and ring thus form a universal joint
or gimbals, which will permit the nozzle to be
turned in any direction inside of a circle.

On the castings, in the rear of the standards,
and directly in line with the nozzle, is a ledge,
upon which is secured a short section of pipe,
the forward end of which is formed into a ball
or spherical head. This pipe is provided with
a bed plate and is secured in the ledge in a way
so it can be adjusted. Around the outside of
the spherical head is placed a soft metal or ex-
pansion packing ring. When the ball is firmly
compressed inside of the socket this ring makes
a tight joint. The ball is kept in its proper
relation to the socket by means of bolts. A
leather packing can also be supplied around
the inner edge of the ball, so as to force against
the inside face of the socket by the internal
pressure of water. The gimbal suspension of
the nozzle and socket will permit their being
shifted to any desired angle inside of a semi-
circle without altering the relation of the ball
or socket and at the same time preserving their
water tight connection.

It will thus be seen that the inventor provides
a joint which is held together and made water
tight solely by external means, thus avoiding
the usual obstructions to the passage of the
stream which are produced when the joint is
held together by bolts or other external devices.

In order to balance the nozzle a shaft is
mounted across the upper ends of the standards
above the joint, so that it will turn freely in
the standards, and on this shaft is secured a drum.
A chain or rope has one end secured to the
nozzle at a suitable point between the joint and
its extreme end. This chain extends back and
passes once or twice around the drum and then
has its opposite end fastened to the drum. A
lever, which extends backward to the desired
length, has its forward end fixed to the end of
the shaft, and a counter weight is arranged to
be suspended from the lever. This weight can
be adjusted to any desired point along the
lever in order to properly balance the weight
of the pipe. This arrangement will preserve a
uniform balance, no difference what position
the nozzle may be moved to, and is therefore a
great improvement on the old lever and weight
balance, whose leverage varied by its being
drawn across its fulcrum according to the eleva-
tion of the pipe.

When this balancing attachment is not used,
the upright standards can be done away with,
and the ring supported on the outer extremities
of two adjustable arms which extend forward,
thus virtually uniting the pipe and nozzle by
strong and firm connection which serves to
preserve their relative positions with each
other. By this construction and application of
the ball and socket joint much of the trouble
heretofore encountered is avoided, and besides,
the inventor does not impair the force and
equality of the stream by a tortuous course or
internal obstructions. It will be noticed that
he provides a gradually decreasing area of
water passage from the inlet of the pipe to the
discharge end of the nozzle, thus preserving
the full effect of the stream.

THE shaft of the Utah mine, on the Comstock,
has been cleaned out to the bottom, and the
tubs, cables, sheaves and other debris of the
burnt hoisting works extracted. The shaft is
sunk to a depth of 584 feet. Sinking has not
yet been resumed owing to a fearful shower
of water that sprang from cracks in the rock on
every side of the shaft with such force that it
is impossible for men to work in it while it
lasts. The pump keeps down the flow of water
with ease, and in a very few days this flow will
be drained sufficiently to permit of a resump-
tion of the sinking.

HEAT ON THE COMSTOCK.—Owing to the in-
tense heat in the main east drift on the 1700-ft
level, arrangements have been made with the
Belcher company to allow the Crown Point to
tap the Belcher air shaft on the 1500-ft level,
and conduct a portion of the fresh air in pipes
down to the 1700-ft level, which will greatly
facilitate the work in that portion of the mine.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANKS.]

There have been many works written, devoted exclusively to descriptions of gems and precious stones.

Pliny, who lived between the years 23 and 79 after the Christian era, was the author of a voluminous work on natural history, translations of which may be found in book stores even in San Francisco. The thirty-seventh and last volume of this great work is devoted to mineralogy and gems. Pliny is the first known author who has written on this subject, but as the ancients know nothing of mineralogy as we understand the sciences, the reader is often at a loss to know what gem he alludes to in his descriptions. He classified gems according to color. In his catalogue he enumerates 135 distinct species.

The art of imitating gems in his day was carried to such perfection that he complains of the extreme difficulty of distinguishing between the false and true. The sardonyx was imitated by cementing three gems of different colors together and cutting them down on the lapidary's wheel. They had a trick also of cementing a plate of rock crystal to a piece of colored glass in such a manner that the surface had the hardness and luster of the crystal and the color of the glass. This imitation stone was then set in such a manner as to hide the edges. They were so skilled in the manufacture and working of glass that they could imitate all the stones and even all the marbles then known.

There were several other ancient authors who wrote of gems, and in our day there are standard works on the subject; some treating of gems *per se*, others containing page upon page of poetical allusions to precious stones without giving the reader much practical information on the subject.

The ancients had strange ideas regarding gems. They believed certain stones had the property of curing diseases, and they were carried about the person, by those who could afford it, to hold certain diseases in check, believing, with the moderns, that "prevention is better than cure."

Quartz crystals were supposed to be water hardened to adamant by long exposure to excessive cold. This belief was strengthened by observing what is not uncommon in crystals of quartz—the presence of drops of water within the crystal walls.

Pliny says: "Rain water and pure snow are absolutely necessary to pure rock crystal." The largest crystal he has ever seen weighed 150 pounds. Blocks of this mineral are found in Switzerland weighing 800 pounds. Very fine specimens are found in California, near Placerville, El Dorado county.

Pliny mentions a fable, common in his day, that the first use of precious stones originated with Prometheus, who was ordered by Jupiter to set a fragment of the rock of Caucasus in a link of his chain, and to wear it as a finger ring as an extension of his punishment after his release.

Gems can only be determined by their physical properties. It is an easy matter for the chemist to analyze any gem if he be allowed first to reduce it to a powder; but as gems are generally found singly, and as the stone, no matter how precious, must be destroyed or injured before an analysis is possible, mineralogists have devised a systematic series of experiments which lead with certainty to the determination of all gems and precious stones. In the description of the individual gems in this paper, the chemical properties are also given, for no description of a mineral substance would be complete without this; but any prospector who finds a stone which he has reason to suspect is precious, should treat it as if it was known to be such. When the rules are known, it will not be found difficult to determine gems, but to do so successfully will require some skill and the exercise of considerable judgment.

In distinguishing gems and precious stones regard must be had to the following properties of minerals: 1, Crystalline form; 2, Hardness; 3, Luster; 4, Diaphaneity; 5, Specific gravity; 6, Electricity; 7, Magnetism; 8, Optical properties; 9, Iridescence; 10, Color; 11, Phosphorescence; 12, Touch; 13, Smell.

(1.) Crystalline form. This constitutes a science by itself, and requires a thorough knowledge of the higher branches of mathematics, beyond the capacity of the ordinary reader.

Although the multitudes of modifications of crystals are so perplexing to the ordinary observer, yet they are all based on certain simple forms, as follows:

(A.) Cube and octahedron—axes 3; rectangular and equal.

(B.) Right prism with square base—axes 3; rectangular, 2 equal.

(C.) Right prism with rectangular or rhombic base. Axes 3, rectangular and unequal.

(D.) Right rhomboidal and oblique rhombic prisms. Axes 3, unequal; 2 rectangular.

(E.) Oblique dysymmetric rhomboidal prism. Axes 3, unequal and unequally inclined.

(F.) Rhombohedron and hexagonal prism.

Axes 4; 3 equal and equally inclined; 1 at right angles with the other 3.

Even this will not be easy to understand without a set of crystal models. Nor is it imperative that it should be understood, as gems are generally known by other properties.

(2.) Hardness of minerals is their power to resist any attempts to separate the atoms of which they are composed. The term hardness is comparative; a series of minerals has been selected, commencing with talc and ending with the diamond, and has by common consent been taken as a "scale of hardness," and by this scale all other minerals are compared. The following is the list: 1, (the softest) talc; 2, uncrystallized gypsum; 3, calcareous spar (a cleavable variety); 4, fluor spar; 5, apatite; 6, feldspar; 7, rock crystal; 8, prismatic topaz; 9, corundum; 10, diamond (the hardest).

To decide the hardness of a mineral, first compare the specimen with No. 5, which is the medium, see then first if it can be scratched by apatite, if not, by the fluor spar; a few experiments of this nature will enable the observer to form a tolerably correct idea of its hardness. The next step is to try the specimen with the edge of a triangular file, holding the specimen on the edge of a table, a grating sound will be produced of more or less intensity

body compared with another of the same magnitude is the specific gravity.

If a cubic foot of water weighs 1,000 ounces and a cubic foot of iron weighs 7,000, their specific gravities as compared to each other is as 1,000 is to 7,000.

As there must be some standard of comparison which is readily available under any and all circumstances, distilled or river water has been adopted by common consent as that standard. It is evident that any body placed in water will displace its own volume of that fluid. That is to say, if a vessel be filled evenly full and a cubic inch of any substance introduced, water would run over which would exactly fill a cubic inch of space. A cubic inch of cork would displace the same volume of water as a cubic inch of gold or platinum. There are mechanical difficulties in this experiment which make it imperfect unless the body is very large. If we weigh a body in the air and then again weigh it suspended in water, it will be found to weigh less than before; this difference is the absolute weight of an equal volume of water. With this data we can readily calculate the specific gravity of any substance either lighter or heavier than water, by the following equations:

For bodies heavier than water—as the loss of weight a body sustains when weighed in

Improved Band Sawing Machine.

Why band saws frequently break is not difficult to understand. Forming, as the delicate thin ribbon of steel does, the sole connection between the pulleys over which it runs, it is obvious that, if one pulley be started into sudden motion, the saw must slip over the other pulley before the inertia of the latter is sufficiently overcome to allow of the imparting to it of a velocity, say of 400 revolutions per minute. Slipping produces friction, friction, heat and crystallization of the steel blade, and hence conditions are determined which, coupled with the strain set up, ultimately may break the saw. At the same time further injury may be done by the rubbing of the blade over the covering of the pulley. Various methods have been tested to avoid this trouble and of these the most common is making the upper wheel less heavy than the lower one. In the machine which we herewith illustrate a new plan is adopted, which admits of both wheels being constructed of the proper strength and weight.

In the rim of the upper cast iron pulley is formed a recess about five-sixteenths of an inch deep, which has a number of projections that are ground to a circle corresponding to the diameter of the wheel. The space between the projections is filled with plumbago, and over all is located a band of steel or other material, rolled true to the diameter of the projections. The band is open and after being placed in position is so closed as to allow of adjustability of its diameter. It is covered with leather or rubber, as desired. With this device, when the lower wheel is started before the inertia of the upper wheel is overcome, the band slides in the recess, rubbing on the projections, and the upper wheel is gradually set in motion without any friction taking place against the saw. As soon as its velocity equals that of the driving wheel the pressure of the band is sufficient to maintain the same, since it requires more power to slide the band on its axis. Now, when a piece of wood is put to the saw, it is obvious that the effect of the band is to equalize the speed of the wheels; and so, also, when the lower wheel is suddenly stopped, the upper one will expend its momentum in running on inside the band, the saw remaining at rest. It is usual to cover the upper wheel with elastic material which, to some extent, yields to the irregularity of motion.

The manufacturers of this machine state that the band referred to forms an excellent elastic bed, as its tendency is to be thrown outward by centrifugal force, in opposition to which is the pressure of the blade.

The use of the band, it is further stated, permits the employment of a direct brake acting quickly and not endangering the lower wheel. To this end an improved clutch brake is arranged, which takes hold of the outside and the inside of the tight pulley rim, pressing at each side with equal force, so that its tendency is not to dislocate either pulley or shaft. By turning a small screw, friction may be increased or diminished, or wear compensated for. The saw guide consists of lateral and back thrust guides or supports. The former are flat pieces of wood on each side of the saw, which may be closed up to the blade and adjusted to compensate for wear. The back thrust guide consists of a series of chilled iron bells, with steel washers, bells and washers lying on each other alternately in a cylindrical inclosure drilled in the cast iron support. The back of the saw comes in contact with the balls through a groove in the cylinder; and as the balls rest only on the edge of small holes made through the supporting washers, all can be brought forward and adjusted to the back of the blade which, passing downward, rotates the bells without them. Devices are added which cause the balls to revolve irregularly, presenting gradually the whole surface of the ball to the support of the blade. By this general arrangement, it is claimed, the friction of the fast passing blade is reduced to a minimum, while heating is avoided.

The last improvement of the tour which constitute the principal features of the invention, is the device for making the adjustment, for steering the saw blade, more sensitive to the varying length of the letter. The short arm of a weighted lever presses against a regulating screw, which passes through horizontal miter gear, and engages therewith, by means of a slot and feather, to a nut on the idler wheel carriage. By turning a hand wheel connected to the miter gear, the carriage is raised and lowered on the guide slide. For changing the plane of rotation of the upper wheel, the journal boxes are connected by a circular flange provided with circular V slides. The latter are engaged and held by a sliding cross-head. Adjustment is made by a worm and screw, and is permanent and not affected by vibration.

This machine is manufactured by Bentel, Mergedant & Co., of Hamilton, Ohio, and received the first premium at the recent Cincinnati Industrial Exposition.

SATURDAY morning, while some men were working in the shaft of the Washington mine, near Hornitos, Merced county, about 30 feet of earth suddenly gave way, and falling upon one of the workmen, named John Williams, killed him instantly.

BENTEL, MERGEDANT & CO.'S BAND SAWING MACHINE.

sity as the specimen is hard or soft. The comparative mineral thought to be of the same hardness, is tested in the same manner until it is quite certain what test mineral is identical with it in point of hardness.

(3.) Luster. This word, as applied to minerals, is expressive of their surface appearance, and does not necessarily indicate high reflective power. There are six different kinds of luster recognized in mineralogy. 1, metallic, the luster of metals; 2, vitreous, like broken glass; 3, resinous, luster of yellow resins; 4, pearly, like pearl; 5, silky, resembling silk; 6, adamantine, the luster of the diamond, which must be seen to be understood.

There are four degrees of intensity to luster. 1, splendid, reflecting well defined images like a looking glass; 2, shining, producing an imperfect image by reflection; 3, glistening, reflecting from surface, but giving no defined image; 4, glimmering, reflecting imperfectly and apparently from points on surface.

A mineral is said to be "dull" when there is a total absence of luster, like a piece of chalk.

(4.) Diaphaneity. This property of minerals permits light to pass through them with different degrees of facility. When the outline of an object seen through a diaphanous mineral is perfectly distinct, the specimen is said to be transparent, for example, a piece of plate glass or a pure quartz crystal. When objects are seen, but indistinctly, (like ground glass), it is said to be semi-transparent. When light is transmitted but objects are not seen, it is translucent, like white wax or stearine. A mineral is sub-translucent when the thin edges only transmit light.

(5.) Specific Gravity. The weight of any

water is to its absolute weight, so is 1 to the specific gravity.

For bodies lighter than water—add a known weight sufficient to sink it in water to its weight in air; then, as the sum of these weights is to its weight in air, so is 1 to the specific gravity.

To take the specific gravity of a mineral, certain appliances will be required, which differ according to circumstances.

If the specimen is larger than an egg, a good common balance will give results sufficiently accurate for practical purposes. But if smaller, the balance must be delicate in proportion.

[To be Continued.]

The pottery and pipe factory at Bnena, Oregon, is quite a large and imposing structure. The main building is 16 by 116 feet, two stories high; the warehouse 40 by 60 feet, and the engine room 40 by 40 feet, and the furnace room 30 by 30 feet. This company proposes to erect a large kiln for the manufacture of pipe for water and sewerage purposes, to supply the increasing demand of Portland and Salem. A vein of fire clay has been tried and proves valuable for the manufacture of fire-brick, which have been in use for some time, and take the place of the English product.

A REPORT was circulated about Austin last week that there was trouble among the miners on Ruby hill. A number of claims are said to have been jumped, and the jumpers maintain a fighting interest thereto. It is stated some shooting had been indulged in, but with what result could not be ascertained.

The Sutro tunnel is now in 12,242 feet.

Mining at You Bet, Nevada County.

The Neere & West, Walooa, Red Dog and the Uncle Sam & Mallory, the latter also includes the Duryea purchase, are in the You Bet mining district, and are owned by an English company. Mr. G. S. Powers is the superintendent.

In the first named claim there is about 25 acres of good ground, which varies in depth from 50 to 250 feet. They are now washing to bedrock through a hedrock tunnel 1,250 feet in length. On the 30th of December a blast of 500 kegs of powder was exploded in drifts in this claim, which loosened up dirt enough for a two months' run. The outlet of this and the Walooa is Bird's Eye canon.

The Walooa contains 90 acres of ground, which varies in depth, but will average 150 feet. In this claim the superintendent is only washing off the surface.
